Volume 01, Nomor 01, Desember 2017

Journal of Stem Cell Research and Tissue Engineering (JSCRTE) is published by Stem Cell Research and Development Center, Airlangga University. Stem Cell Research is dedicated to publishing high-quality manuscripts focusing on the biology and applications of stem cell research. Submissions to Stem Cell Research, may cover all aspects of stem cells, including embryonic stem cells, tissue-specific stem cells, cancerstem cells, developmental studies, genomics and translational research. Special focus of JSCRTE is on mechanisms of pluripotency and description of newly generated pluripotent stem cell lines.

Editor In Chief

EDITORIAL ADDRESS

Stem Cell Research and Development Center

Institute of Tropical Disease in Building, Jl. Mulyorejo Kampus C Unair 60115 East Java

Indonesia Phone +62 822-3268-7366, E-mail : journalofscrte@gmail.comOJS : <https://e-journal.unair.ac.id/JSCRTE>**Publication Schedule**

The Journal of Stem Cell Research and Tissue Engineering is published regularly twice a year in December and May.

Manuscript Submission

Manuscript should be written in MS Words format. Figure, illustration and picture included in the manuscript file.

Manuscript Publishing

Feasible manuscript was determined by Editorial Board after obtaining recommendations from peer reviewer. Manuscript revision is author responsibility and manuscript that are not feasible will be returned to the author

ABSTRACT

Maxillofacial bone defects due to tumor resection, trauma or infections should be reconstructed to maintain the bone continuity in order to preserve its masticatory, speech and esthetic functions. Autogenous bone graft have been the gold standard for mandibular defects reconstruction, however, it is associated with limitation in volume and availability as well as the donor site morbidities. Tissue engineering approach has been proved to be a good alternative to overcome the limitation of autogenous bone graft. Tissue engineering studies have been conducted combining various sources of mesenchymal stem cell, scaffolds, and or signaling molecules. The paper aims to provide information on the development of bone tissue engineering researches to reconstruct bone defects through results of numerous studies obtained in the English literature. As the conclusion, bone tissue engineering is a potential approach to reconstruct maxillofacial bone defects.

Keywords: scaffold, osteoconduction, mesenchymal stem cell, bone regeneration, bone integration.

Introduction

Surgical reconstruction of critical size mandibular defect has been a great challenge in oral and maxilla facial surgery. Gold standard for mandibular reconstruction is autogenous bone graft. However, autogenous bone graft has limitation in shape, size, and its availability; furthermore, it has been attributed to donor site morbidity (Arrington *et al.*, 1996; Heary *et al.*, 2002). While the transfer of autologous tissue such as bone grafts or tissue free flaps are well-described, they are not without complications. To overcome these limitation, one can expect more on bone tissue engineering. Tissue engineering or tissue regeneration is a multidisciplinary approach to replace tissue loss as a result of

traumatic defects, tumor resection or infection (Srisuwan *et al.*, 2000). The prospect of using principles of tissue engineering to reconstruct defects in oral and maxillofacial defects continues to gain the attention of the reconstructive surgeon. (Susarla *et al.*, 2011) Numerous studies in bone tissue engineering have attempted to search for effective combination of stem cells, scaffolds, and signaling molecules for reconstruction of bone defects in various animal models. A tissue engineering approach provides numerous prospective benefits, including a decline in donor site morbidity, a decrease in procedural sensitivity of the repair, and the capacity to intimately mimic the *in vivo* tissue environment

into recapitulate normal craniofacial development (Ward *et al.*, 2010). The paper aims to provide information on the development of tissue engineering to reconstruct maxillofacial bone defects.

Principles of tissue engineering

Principles of tissue engineering are basically a triad of stem cells, signaling molecules, and scaffolds or extracellular matrix (Figure 1). (Rai *et al.*, 2015). A stem cell is defined as an unspecialized cell that can renew and maintain itself for a longer period of time with the potential to commit to a cell or tissue lineage with specialized functions. The use of stem cells, either embryonic or adult-derived (ADSCs), is a reality of regenerative medicine and dentistry. ADSCs are multipotent cells not derived from embryonic or primordial germ cell lineage, and they have the potential to differentiate into bone, muscle, cartilage, nerve, and vasculature under appropriate conditions (Conrad *et al.*, 2005). These stem cells can differentiate into various cells like chondrocytes, osteoblasts, myoblasts, hematopoietic cells, and neural cells (Figure 2).

Signaling molecules: Various growth factors and cytokines are mixed to the ECM, like bone morphogenetic proteins (BMP), fibroblast growth factor-2 (FGF-2), interleukin-6, insulin-like growth factor (IGF), platelet-derived growth factor (PDGF), transforming growth factor- β 1,

etc. This co-localization works as a storage pool of growth factors and may diminish growth factor degradation, protecting them from the local micro environment while facilitating the presentation of the growth factors to cell surface receptors (Schnaper *et al.*, 1993; Roberts *et al.*, 1988).

Scaffold: A scaffold is a permanently or temporarily placed three-dimensional porous and permeable natural or synthetic biomaterial that is biocompatible. It can be natural (Figure 2) or synthetic. It acts as a matrix and allows the attachment, migration, and differentiation of progenitor cells. Properties of scaffolds (such as biodegradability, porosity, stiffness, and strength) influence cell adhesion, migration, and proliferation (such as osteoconduction). The greatest challenges faced in tissue-engineered devices, regardless of tissue type, is promoting healing in three dimensions. Scaffolds have been made-up with a variety of innate and synthetic biomaterials, such as ceramics, metals, proteins, and polymers. An appropriate scaffold for tissue engineering will be one that is created with biology in mind. The function of the scaffolds is providing structural support to cells, reservoir for growth factors and provide flexible, physical environment for remodeling (Patil *et al.*, 2013).
