Keywords: Clinical dental student, Behavior, Hand hygiene, Personal protective equipment, Standard precaution

Abstract: Standard precaution behavior is meant to reduce the risk of transmission through blood-borne pathogens from both recognized and unrecognized sources in dental healthcare services. Hand hygiene and personal protective equipment are two major components of standard precautions that are believed to be the most effective methods to prevent the transmission of pathogens associated with healthcare in dental healthcare workers. The purpose of this study was to investigate the behavior of standard precautions among clinical students in RSGMP FKG Unair and to describe the factors that can influence behavioral activity. This research is a descriptive observational study with a cross-sectional design among 100 clinical students in RSGMP FKG Unair. The data was collected using direct observation, and interviews. The data was then distributed in table form, then analyzed with the SPSS program. The results show that the variables of supervision, facilities, knowledge, treatment types and gender have an odd ratio > 1 , except that supervision and facilities have a p-value < 0.05 , which is p-value 0.001 for supervision and p-value 0.023 for facilities. From the research among 100 clinical students, 54% of the respondents had a higher score than average. The average score of standard precautions behavior is about 71.8% or 3.59 out of 5 so it can be concluded that the behavior of standard precautions among clinical students in RSGMP FKG Unair is in need of improvement.

1 INTRODUCTION

Cross-infection can be defined as the transmission of infectious agents between patients and staff within a clinical environment (Lugito & Manuel, 2013). Dental health personnel (DHP) are at high risk of exposure to cross-infection with blood-borne pathogens, such as hepatitis B virus (HBV), hepatitis C virus, and human immunodeficiency virus (HIV), and other viruses and bacteria that colonize the oral cavity and the upper respiratory tract (WHO, 2008). This risk is enhanced by accidental injuries caused by dental instruments during patient treatment. Such infections can be prevented using safety precautions and implementing infection control guidelines in addition to vaccination and proper post-exposure management (Lugito & Manuel, 2013).

According to the WHO in 2008, two million health workers in the world were exposed to hepatitis B, nine hundred thousand health workers were exposed to hepatitis C, and three hundred thousand health workers were exposed to HIV

(WHO, 2008). In addition, based on the data collected by the Ministry of Health in 2010, 8,786 cases of HIV due to injection were recorded and the risk of HIV to be transmitted from HIV-infected syringes is 0.04%, while the risk of hepatitis B transmission is 27-37% (Depkes RI, 2008).

Associated with Bloem's theory, health degree is influenced by four factors: environment, health service, heredity, and behavior. So, dentists including clinical dental students need to be aware of disease exposure in the work environment. Standard precaution behavior is meant to reduce the risk of transmission through blood-borne pathogens from both recognized and unrecognized sources in dental healthcare services (Notoatmodjo, 2012).

According to Green, a person's behavior is influenced by a number of factors namely knowledge, attitude, and belief (predisposing factors). In addition, the availability in terms of facilities (enabling factors) and attitude of health workers (reinforcing factors) also support and

strengthen the formation of behaviour (Notoatmodjo, 2012).

There has been no previous study on the descriptive overview of standard precaution behavior among clinical students in RSGMP FKG UNAIR; hence, this study is expected to comprehend the descriptive overview of standard precaution behavior among clinical students in RSGMP FKG UNAIR as seen from the factors influencing the behavior. Standard precautions to be studied are hand hygiene and use of personal protective equipment, in accordance with the WHO which mentions that hand hygiene and the use of personal protective equipment are the effective first steps in preventing disease transmission in healthcare (WHO, 2008).

2 MATERIALS AND METHODS

This research is a descriptive observational research with a cross-sectional design. The number of samples studied were 100 respondents with the sampling technique of random sampling. The data was collected using two methods: interview and behavioral observation. Data collection through interviews was conducted in order to comprehend the knowledge level, gender, semester level, and type of treatment. Meanwhile, observation was conducted in order to determine the behavior, availability of facilities, and supervision by health workers. Clinical dental students in RSGMP FKG UNAIR who were conducting treatment on patients were observed by the researcher without the respondent knowing and then the researcher interviewed the students. The data obtained was then processed and analyzed using the SPSS program.

3 RESULTS

Data on the distribution of the respondents' characteristics is shown in Table 1. Table 1 contains the characteristics of 100 respondents; 78 respondents (78%) were female. Based on the semester level, the respondents in the 9th semester numbered 53 (53%) and in the 11th semester 47 (47%). Based on the type of treatment performed, safe treatment was performed by 79 respondents (79%) and risky treatment was performed by 21 respondents (21%).

Table 1: Distribution of the respondents according to gender, semester level and treatment type.

Variables	Category	Amount	Percentage
Gender	Male	22	22%
	Female	78	78%
Semester Level	9th Semester	53	53%
	11th Semester	47	47%
Treatment types	Risky	21	21%
	Safe	79	79%

Table 2: Distribution of the respondents according to knowledge level.

Knowledge level	Frequency (n)	Percentage (%)
> average	63	63%
≤ average	37	37%

From the result, the average knowledge level of the respondents was 76.3%. Furthermore, the distribution of the respondents' knowledge level was categorized into above average knowledge and less than or equal to average knowledge. The following is the distribution of respondents based on the knowledge level of the standard precaution.

Table 3: Distribution of the respondents according to availability of facilities and supervision.

Variables	Category	Amount	Percentage
Availability of facilities	Sufficient	38	38%
	Insufficient	62	62%
Supervision	Conducted	22	22%
	Not conducted	78	78%

Table 3 describes the distribution of the respondents according to the availability of standard precaution facilities and supervision by health workers. Based on the table, it is seen that the majority of the respondents (62%) worked within a cubicle with insufficient facilities. Similarly, the majority of the respondents (78%) worked without any supervision from health workers.

Table 4: Distribution of the respondents according to standard precaution behavior among clinical students in RSGMP FKG Unair.

Standard Precaution Behavior	Yes (%)	No (%)
Hand hygiene	56%	44%

Using personal protective equipment - masks	95%	5%
Using personal protective equipment - gloves	99%	1%
Using personal protective equipment - lab coats	100%	0%
Using personal protective equipment - safety glasses or goggles	9%	91%
Average	71.8 %	28.2%

From the result, the average score on standard precaution behavior of the respondents was 71.8%. Moreover, the distribution of respondents' behavior was categorized into above average behavior and less than or equal to average behavior. The following is the distribution of the respondents based on standard precaution behavior.

Table 5: Distribution of the respondents according to category of standard precaution behavior among clinical students in RSGMP FKG UNAIR.

Behavior score	Frequency (n)	Percentage (%)
> average	54	54%
≤ average	46	46%

Based on the table, it is seen that the majority of the respondents (54%) had above average standard precaution behavior.

Table 6: Distribution of the respondents according to Gender, Semester Level, and Types of Treatment related to Standard Precaution.

Variables	Categories	Behavior		P Value Odd Ratio
		≤ Average	> Average	
Gender	Female	36 (46.2%)	42 (53.8%)	P Value 0.954 Odd Ratio 1.029
	Male	10 (45.5%)	12 (54.5%)	
Semester level	9 th Semester	23 (43.4%)	30 (56.6%)	P Value 0.579 Odd Ratio 0.800
	11 th Semester	23 (48.9%)	24 (51.1%)	
	Risky	7 (46.0%)	14 (73.3%)	

From the table, it can be seen that the female and male respondents equally had above average

behavior as well as seen from semester level; 9th semester and 11th semester students equally had above average behavior. If seen from type of treatment, the respondents with risky treatment had above average behavior compared to the respondents with safe treatment.

However, the result of p value for the three variables > 0.005 meaning that gender, semester level, and type of treatment were not significantly related to the standard precaution behavior among clinical students in RSGMP FKG UNAIR.

Table 7: Distribution of the respondents according to Knowledge Level, Availability of facilities, and Supervision by health workers related to Standard Precaution Behavior.

Variables	Categories	Behavior		P Value Odd Ratio
		≤ Average	> Average	
Knowledge level	≤ average	21 (56.8%)	16 (43.2%)	P Value 0.098 Odd Ratio 1.995
	> average	25 (39.7%)	38 (60.3%)	
Availability of facilities	Insufficient	34 (54.8%)	28 (45.2%)	P value 0.023 Odd Ratio 2.631
	Sufficient	12 (31.6%)	26 (68.4%)	
Supervision by health workers	Not conducted	43 (55.1%)	35 (44.9%)	P value 0.001 Odd Ratio 7.781
	Conducted	3 (13.6%)	19 (86.4%)	

Based on the table, it is shown that the respondents with above average knowledge had above average behavior; otherwise the respondents with less than or equal to average knowledge had less than average to average behavior.

From the availability of facilities, the respondents with insufficient facilities had less than average behavior; otherwise the respondents with sufficient facilities had above average behavior. Similarly, the respondents with supervision by health workers had above average behavior compared to the respondents without supervision by health workers.

Of the three variables, the p value for the availability of facilities and supervision < 0.005 meaning that the availability of facilities and supervision by health workers significantly correlated with the standard precaution behavior among clinical students in RSGMP FKG UNAIR.

4 DISCUSSION

The result of the research shows that the average standard precaution behavior was 71.8% or 3.59 of the total value of 5 with the standard deviation of 0.648. Such score is lower than the standard set by the WHO, whereas hand hygiene and the use of personal protective equipment are the most important components in terms of standard precautions which is the basis for prevention and control of disease transmission in health services.

In addition, 54 out of 100 respondents had above average behavior in terms of implementing standard precautions. This number is somewhat small, given the risks faced. The result of the study conducted by Ningrum shows that the compliance level among clinical students in RSGMP UMY regarding the use of personal protective equipment was 91.7% as well as Setiana's which found the level of infection prevention in UNDIP students of 98.1%. Compared to the previous studies, it can be stated that the behavior of prevention and control of disease among clinical students in RSGMP FKG UNAIR remains lacking.

Lack of such behavior is seen from the minimal use of personal protective equipment, namely safety glasses or goggles (Table 4). The result of the study was obtained from 22 risky treatments, 9 of which used safety glasses during the procedure. Safety glasses are worn during the treatment of scaling, curettage, and exodontias due to the fact that such treatments are prone to aerosol contamination and sprinkling of body fluids (blood and saliva). Furthermore, safety glasses were mostly worn by females (6 respondents) rather than males (3 respondents). This is due to the fact that females have the characteristics of maintaining their physical appearance, especially the face, so that they pay more attention to the work environment.

Some students performed risky treatment without using safety glasses; this is due to the lack of self-awareness of the students regarding the importance of maintaining personal safety during work. Besides safety glasses or goggles, hand hygiene behavior is also the standard precaution behavior which is still underestimated by clinical students (Table 4). This is possibly caused by insufficient hand hygiene facilities (Table 3). The lack of such facilities includes the unavailability of antiseptic soap in each cubicle and faucets which do not function, so that the students are reluctant to wash their hands after the treatment.

According to Lawrence Green's theory, adequate knowledge as a predisposing factor should be

followed by good and right behavior. However, as a matter of fact, out of 63 respondents with above average knowledge, 25 had less than average behavior (Table 7). This may be due to the lack of sufficient facilities as it is known that the availability of facilities as an enabling factor also influences respondents' behavior. If students with above average knowledge are not supported by the availability of sufficient facilities, it will result in less than average behavior.

The relation between facilities and standard precaution behavior is shown by the p value of 0.023 and odds ratio of 2.631 meaning that if the facilities are sufficient, the respondents have the opportunity of 2.631 times in order to behave above average compared to the respondents with insufficient facilities.

The result is in accordance with Lawrence Green's theory stating that a person's behavior is influenced by enabling factors, such as the availability of facilities. Without sufficient facilities, one will not be able to apply good behavior. Similar to this study, in implementing the standard precaution behavior as an effort to prevent disease in the work environment, sufficient facilities are required. Clinical students tend to implement standard precautions as an effort to avoid disease transmission if hand hygiene facilities are available in the workplace. In addition, the availability of facilities must also be supported with sufficient facilities, so that they are able to improve good behavior in implementing standard behavior.

Besides facility factors, the lack of supervision by health workers regarding standard precautions also affects student behavior. Such factor plays an important role in the standard precaution behavior among clinical students in RSGMP FKG UNAIR which means that if behavior is explained through the supervision of standard precautions, there was a difference between the supervised and the unsupervised respondents. This is supported by the statistical test result of the p value which is 0.001 and odds ratio which is 7.781 meaning that if supervision is provided, the respondents have 7.781 more chances to behave above average compared to unsupervised respondents (Table 7).

The purpose of supervision is to eliminate or minimize unexpected behavior. Through supervision, the students will behave in accordance with the procedure in terms of implementing standard precautions as an effort to prevent disease in the workplace. This is due to the fear or pressure (enforcement) in the students of punishment if they do not perform standard precautions.

Such emphasis approach leads to a faster impact on behavioral change, but generally such behavioral change is not sustainable due to the fact that such behavior is not based on a high level of knowledge and awareness regarding the purpose of the behavior. Looking at the result of the study (Table 5.3), the majority of the respondents remained working without supervision by health workers, whereas the lack of supervision can possibly lead to the risk of degraded behavior, and vice versa.

5 CONCLUSIONS

From the result of the study on 100 clinical students, it can be concluded that 54% of the respondents were above average. With the average standard precaution behavior of 71.8% or 3.59 out of 5, this is considered low. Thus, the standard precaution behavior among clinical students in RSGMP FKG UNAIR needs improvement.
