Journal Information

This peer reviewed Journal was created in 1996 by practitioners, mental health program managers and mental health consumers to provide international practitioners, scholars and consumers with a forum to publish and discuss their work in program development, evaluation research, policy innovations, and therapeutic practices that have been successful in their particular region and cultures. IJPR is not associated with any university or governmental institution, nor is it part of any ‘old boy’ or other professional network. It was created to provide information to an international readership about issues related to psychosocial rehabilitation and associated topics.

Articles on psychosocial interventions, psychopharmacotherapy, mental health primary care, institutional and community care innovations, decentralization, policy changes, community & regionally based systems, and program evaluation are given particular attention. However, all articles that relate to psychosocial rehabilitation will be considered.

We invite comment from all readers on any and all subjects published in this journal, including the journal format itself. Feel free to comment on the Bulletin Board as well.

Effect of Dual-Task Net Step Exercise on Working Memory, Global Cognitive Function and Brain Derived Neurotrophic Factor Serum Levels in Elderly with Mild and Moderate Cognitive Impairment

Subagyo, Imam Subadi, Asri Sulistyaningrum, Purwo Sri Rejeki, Meissy Andriana

ABSTRACT—Background: Mild and moderate cognitive impairment in elderly lead to activity limitation and decrease quality of life. Brain derived neurotrophic factor (BDNF) levels is decreased in elderly with cognitive impairment. Physical exercise can promote cognitive function improvement. One of the mechanisms is through BDNF.

Objective: Analyzed the effect of dual-task Net Step Exercise (NSE) on working memory, global cognitive function and BDNF serum levels in elderly with mild and moderate cognitive impairment.

Method: The study was pretest-posttest control group design, which enrolled 26 elderly subjects with mild and moderate cognitive impairment, 13 subjects in intervention (dual-task NSE) group and 13 subjects in control group. Before and after study working memory, global cognitive function and serum levels of BDNF was examined quantitatively with enzyme linked immune-sorbert assay (ELISA).

Result: There was improvement of mini-mental state examination (MMSE) score ($p=0.001$) and trail making test-B (TMT-B) score ($p=0.03$) in intervention group after 8 weeks of dual-task NSE, while there was no improvement in control group. There was significant elevation of BDNF serum levels in intervention group after 8 weeks of dual-task NSE ($p=0.001$) while there was no significant change of BDNF serum levels in control group ($p=0.107$).

Conclusion: Dual-task NSE could improve working memory and global cognitive function and also increase BDNF serum levels in elderly with mild to moderate cognitive impairment.

Keywords—BDNF, cognitive impairment, elderly, NSE

1. INTRODUCTION

Mild to moderate cognitive impairment (MCI) is the intermediate stage between cognitive changes of normal aging and dementia. Human and animal studies have converged on the idea that physical exercise may beneficial for brain health and cognition. This effects achieved by certainly multiple reasons such as increase the flow of oxygen-rich-rich blood to the brain, stimulates neurogenesis and promote brain and synaptic plasticity (Cotman and
International Journal of Psychosocial Rehabilitation, Vol. 24, Issue 02, 2020
ISSN: 1475-7192

Berehtold, 2002; Blondell, Hammersley-Mather and Veeraman, 2014). Working memory is part of cognitive system for temporarily storing and managing the information required to carry out complex cognitive tasks. Important information is gradually transferred from short-term into long-term memory. The more the information is repeated or used, the more likely it is to eventually end up in long-term memory, or to be retained. In elderly, neurodegenerative process deprives memory span (Mundkur, 2005).

A meta-analysis study has concluded that activity consist of both motoric and cognitive stimulation, in example dual-task activity, related to improvement of cognitive performance in elderly. The mechanism underlying is enhancement of long-term potentiating (LTP) process of memory, which persistent increase of synaptic strength following high-frequency or repetitive stimulation of a chemical synapse (Erickson et al., 2010; Smith, Nielson and Antuono, 2013).

A number of studies have provided evidence that physical exercise can promote brain derived neurotrophic factor (BDNF), a certain protein generated in neurons, muscle and hematopoietic (Yulinda et al., 2019) that plays role in neuronal survival and synaptic plasticity which are essential for learning and memory (Bathina and Das, 2015). BDNF found in high concentrations in the central nervous system, primarily in the brain regions of the hippocampus, cerebral cortex, hypothalamus, and cerebellum (Praag et al., 2005; Smith, Nielson and Antuono, 2013). Central BDNF can cross the blood-brain barrier and therefore be stored in other areas of the body. BDNF has been implicated in neural development and functioning, including neurogenesis, dendritic growth, and long-term potential of neurons (Yamada and Nabe shima, 2003). Given the evidence for BDNF increases, exercise can be viewed as a potential strategy for increasing BDNF activity for application to the enhancement of cognition (Szuhan, Bugattia and Otto, 2015).

Net step exercise (NSE) is a novel dual-task walking program uses a net and features slow and low-impact physical movement and cognitive activity. In previous study dual-task NSE has been proven improve cognitive performance in healthy elderly. Dual-task NSE program has not been conducted in elderly with cognitive impairment subjects before. There were no previous study that examined BDNF serum levels after dual-task exercise, in particularly dual-task NSE. Therefore, this study aimed to analyze the effect of dual-task NSE on working memory, global cognitive function and BDNF serum levels as marker of cognitive function (Kitazawa et al., 2015; Szuhan, Bugattia and Otto, 2015).

II. METHODS

This study was a non-randomized pretest and posttest control group design. The study was conducted in two nursing home care in Surabaya, WredaUndaan Nursing House and WredaJambangan Nursing House, February-April 2018. Twenty-six elderly men and women who fulfilled the inclusion criteria were enrolled in the study. The intervention and control group consist of 13 subjects each. Subjects in intervention group received dual-task NSE twice a week for 8 weeks, while control group received education about mental health in elderly.

Inclusion criteria were men or women aged 60-75 years, mini-mental state examination (MMSE) score 15-26, good hearing and vision function, can understand and follow verbal instructions well, independent ambulation without assistive device, willing to participate in this research by signing the informed consent after obtaining an explanation. Criteria of drop out were less than 75% of total attendance should be followed, hemodynamic disturbance symptonize with fatigue or excessive sweating, drowsiness, tightness, pallor, or pulse rate exceeding the maximum

DOI: 10.37200/IJFR/V24I2/PB200733
Received: 05 Jan 2020 | Revised: 20 Jan 2020 | Accepted: 30 Jan 2020

4037
heart rate, oxygen saturation < 95% or decrease 4 from baseline, blood pressure > 160/100, the subject declares to resign, died.

Trail Making Test Part B (TMT-B) were used to assessed working memory function. This test consists of 25 circles distributed over sheet of paper. The circles include both numbers (1-13) and letters (A-L). Subjects were asked to draw line to connect the circles in an ascending pattern, but with added task of alternating between the numbers and letters, as quick as possible without lifting the pen from paper. If subject makes an error, examiner has to point it out immediately and allow the subject to correct it. The time (in second) start from first circles after the end of circles counted as the TMT-B score. Global cognitive function was assessed with MMSE, and the BDNF serum levels was assessed one day before subjects began the exercise. BDNF levels in this study was measured quantitatively with enzyme linked immune-sorbent assay (ELISA) using reagentsQuantukine ELISA Human Free BDNF (R&D System, Inc. Minneapolis, USA) Cat: DBD00, Lot: P166314, ED: @*th March 2019. Subjects were reevaluated after eight-weeks.

The dual-task NSE was conducted with 1 or 2 people at a time were required to walk carefully, but rhythmically from one end of the Fumanet to the other without stepping on the ropes or being caught in themat. All participants were required to repeat the step designs in exactly the same way as their instructors. Throughout the 8-week NSE program, the difficulty of the step designs and the number of steps required in each session were gradually increased(Kitazawa et al., 2015).

The statistical analyses were performed by using SPSS version 22.0 program. The differences in the parameters after the treatment were determined by using paired-sample t-test or Wilcoxon signed-rank test. The differences between the groups were determined by using independent-sample t-test and Mann–Whitney U-test. The p values less than 0.05 were accepted as statistically significant.The ethical appeal is submitted to the Medical Research Ethics Committee of the Faculty of Medicine, Airlangga University.

III. RESULT

All subjects received evaluation according to a predetermined schedule. No side-effects were found during and after intervention. Table 1 shows the characteristics of research subjects in both groups. Data analysis showed no significant differences in age, sex, body mass index (BMI), levels of education, MMSE score before intervention, but significant difference in TMT-B score between two group before intervention.

Table 2 shows changes of MMSE score and TMT-B score before and after treatment in both groups. The result of the intervention group which has been performed by dual task NSE shows the significant difference result. Table 3 shows that the change (delta) of MMSE score in intervention group significantly different with change (delta) in control group ($p = 0.009$). Change (delta) in TMT-B score was counted in percentage due to the homogenous baseline. TMT-B score between two groups before exercise. The change (delta) of percentage of TMT-B score in intervention group significantly different with change (delta) in control group ($p < 0.001$).

Table 4 shows changes in BDNF serum levels before and after intervention in both groups. The BDNF serum levels mean in intervention group shows significant elevation of BDNF serum levels ($p < 0.001$). There is no significant change of BDNF serum levels in this group ($p = 0.107$). Significant different of change (delta) between intervention and control group ($p = 0.004$) showed in Table 5.
IV. DISCUSSION

The result of recent study has showed improvement in MMSE score after 8 weeks program in intervention group, but not in control group. There was also significant decreased of TMT-B score after program in intervention group. This means less time needed to finish the TMT-B worksheet, means improvement of time reaction and working memory. There were significantly difference between two groups in the change (delta) of MMSE score. Change in TMT-B score between both groups could not assessed in its absolute value because there was in homogeneity TMT-B score in both groups before program, so the change was analyzed in percentage. There was improvement of TMT-B score for about 13.09±11.518% in intervention group, while in control group there was more time needed to finish the TMT-B worksheet for about 1.16±9.67% compares with before program. The result of the study is supported previous study from Kitazawa et al 2015 that conducted dual-Task NSE once a week for eight weeks in 60 healthy elderly subjects more than 70 years old in which found improvement of cognitive function about 6.8% (Kitazawa et al., 2015).

All subjects in the study might follow other activity in their nursing home. Subjects in control group received education about mental health in elderly once in the beginning of the study and permitted to do their daily activities as before without receiving dual-task NSE program. There was no drop out and no reported incident of joint pain, fall or emergency until the end of study. The study conducted at two different nursing home to avoid interventional bias. Elderly subjects were recruited from nursing to have similarity in physical activity levels and nutritional intake.

According to statistical analysis, characteristic of sex, age, BMI, education, MMSE score, and BDNF serum levels were homogen between two groups. The exception was in TMT-B score that showed better score in control group. It can be caused by many factors. Some literatures have reported relationship between age and BDNF. In human, BDNF levels in circulation decreased significantly with increasing age. BDNF may be modulated in human through body composition. Study in 17 overweight and obese subjects that underwent 3 months of caloric restriction has showed increasing BDNF serum levels after program (Lommatzsch, 2005; Siuda, 2017).

In study that enrolled 118 healthy subjects, there were no difference of BDNF serum levels between males and females. Otherwise, a cross sectional study involved 4463 elderly subjects had found significant difference of BDNF serum levels between males and females. This is caused by hormonal difference (Lang, 2004; Lommatzsch, 2005; Shimada et al., 2014). Levels education, in means length of formal study counting from elementary education, will affect cognition that related to BDNF serum levels also. A study has reported association between low BDNF serum levels with lower cognitive test scores (Shimada et al., 2014).

A functional MRI study has compared neural activities before and after dual-task exercise. The study showed decreased magnitude neural activities at several activated brain region and convergence of neural activities at prefrontal cortex area in the end of dual-task exercise training. This phenomenon representation cortical reorganization process involved neural efficiency after dual-task training become adept and specific.

The result of the change of BDNF serum levels after dual-task NSE showed significant elevation of 4828.23±3069.31 pg/ml of BDNF serum levels in intervention group after dual-task NSE; otherwise no increased in control group. A meta-analysis study has reviewed 29 studies about effect of physical exercise on peripheral BDNF levels and conclude that aerobic type of exercise could increase plasma and serum BDNF, but not with resistance exercise (Ding, 2011).
The normally very high concentration of BDNF in blood could be derived not only from the brain but also from peripheral sources, since body tissues express this growth factor. Given that cerebral BDNF crosses the BBB, it is reasonable to assume that the serum BDNF concentrations are associated with BDNF levels in the brain. The assumption is substantiated by animal experiment showing that BDNF serum levels are correlated with BDNF expression in cortical region (Gass, 2010).

Complex motor movement based physical exercise such as dual task has components motor learning, sensory integration, visual tracking and visual scanning. Motor learning or motor skill is body or extremities voluntary purposeful movement. There are attention and concentration needed in that motions. During the movement, vestibular system also stimulated, which can activate the formation reticularis at the brainstem and selecting relevant – irrelevant information and create awareness that support attention and concentration. Sensory integration is the brain ability to organize the information received from all body sensory modalities including auditory, visual and balance stimulations. Visual scanning and tracking are ability to observe and following the track. This component stimulates eye-extremities coordination.

Dual-task NSE is structured physical activity consist of complex motor movement that rich of stimulation and need attention and concentration. As example, when subject practicing NSE, they would miss the handclapping if they were concentrating on stepping over the net. However, if they were concentrating on handclapping, they would step incorrectly. Consequently, subject in the right square watching the net to perform the exercise correctly. Subjects also had to learn new step design each week. The limitation of this study is that assessment and monitoring of physical and social activity before and during study did not delivered. Post study evaluation of cognition and working memory function was done by the researcher no emerge examiner bias. Further study must be conducted in randomized design.

V. CONCLUSION

Dual-task NSE twice a week can improve the working memory and cognitive function and also elevate the BDNF serum levels in elderly with mild moderate cognitive impairment.

I have published my article in your International Journal of Psychosocial Rehabilitation, Vol. 23, Issue 04, 2019 ISSN: 1475-7192

But it is not indexed in Scopus which is very shocking for me.
I want a correct reply from you dont send me the same story to contact Scopus.

---

Adil Issa Wazni 5 days ago

But it is not indexed in Scopus which is very shocking for me.

Melanie Ortiz 4 days ago

Dear Adil,

thank you very much for your comment, unfortunately we cannot help you with your request. We suggest you contact Scopus support:
https://service.elsevier.com/app/answers/detail/a_id/14883/kw/scimago/supporthub/scopi
Best Regards, SCImago Team

Dr. X. John Paul 1 week ago

Is your journal Scopus indexed currently?

Melanie Ortiz 1 week ago

Dear Dr. X. John Paul,

Thank you very much for your comment. All the metadata have been provided by Scopus /Elsevier in their last update sent to SCImago, including the Coverage's period data. The SJR for 2019 was released on 11 June 2020. We suggest you consult the Scopus database directly to see the current index status as SJR is a static image of Scopus, which is changing every day.
Best Regards, SCImago Team
