Article history:	ABSTRACT				
Received:	Obesity is related to the over-expression of pro-inflammatory cytokines and				
9 March 2019	causes chronic systemic inflammation. The identification of dietary intake				
Accepted:	at risk of inflammation led to optimal interventions. The aim of this study				
20 September 2019	was to determine the correlation between dietary intake and the				
Keywords:	inflammatory biomarker in adolescents with obesity.				
Obesity;	A cross-sectional study was performed on adolescents with obesity at the				
Dietary intake;	Pediatric Nutrition Clinic of Dr Soetomo General Hospital, Surabaya from				
Adolescents;	July to October 2018. Dietary intake was obtained from food recall. The				
HsCRP;	assessment of high sensitivity CRP (hsCRP) was performed using ELISA.				
Inflammatory markers.	Statistical analysis was performed using a correlation test with $p<0.05$ indicating significance.				
	A total of 59 adolescents were included, 32 (54.2%) of which were male and				
	27 (45.8%) were female. The age range was 13–16 years. The mean calorie				
	intake was 1955.9 \pm 778 calories, and the mean hsCRP level was 2308.83 \pm				
	470.95 ng/ml. There was no correlation between total calories, carbohydrate,				
	protein, and fat level intake and hsCRP (p>0.05). No substantial effect of				
	dietary intake was found for hsCRP.				

1.Introduction

In developing countries, the prevalence of obesity has increased in all age groups (Rachmi et al., 2017). The cause of obesity is energy imbalance between energy intake and energy expenditure. Diet is important in the development and progression of obesity.

Obesity is related to chronic low-grade inflammation (Lee et al., 2013) and oxidative stress (Paltoglou et al., 2017). Chronic inflammation causes metabolic disease (Castro et al., 2017). Abdominal obesity is a predictive factor of cardiometabolic risk (Amato et al., 2013). Even in obese individuals with a healthy metabolic state, they are at an increased risk of long-term mortality (Kramer et al., 2013). Over-nutrition is associated with immuneactivation and inflammatory conditions (Lee et al.. 2013). Dietary excess produces an accumulation of lipids in adipocytes (Gómez-Hernández et al., 2016). Excess weight has an inflammatory effect (García-Hermoso et al., 2016). However, exercise can reduce the systemic inflammation associated with obesity (Sirico et al., 2018). The complications of obesity are due to metabolic disorder induced by an excessive accumulation of fat, which leads to cardiovascular disease (CVD) and type 2 diabetes mellitus (Morandi and Maffeis, 2014). Diet and nutrition are modifiable variables in obesity (Hale et al., 2015). The aim of this study was to determine the correlation between dietary

intake and inflammatory biomarkers (hsCRP) in adolescents with obesity.

2. Materials and methods

This is a cross-sectional study conducted at The Pediatric Nutrition Clinic of Dr Soetomo General Hospital, Surabaya from July to October 2018.

2.1. Samples

Adolescents (age 13-16 years old) with obesity were enrolled. The following exclusion criteria were applied: (a) steroid or medical therapy, (b) hormonal therapy, (c) alcohol consumption, (d) smoking, (e) infection, (f) a medical history including an endocrinology immunological disorder. disorder. cardiovascular disease, or other known chronic pathology, and (h) secondary obesity (having a medical condition that causes gain weight). Health status was obtained through self-report to exclude acute and chronic diseases. The study procedures and objectives were explained to the parents and informed written consent was obtained from all participants before they were enrolled. This study was approved by the Ethics Committee in Health Research of the Dr Soetomo General Hospital, Surabaya.

2.2. Anthropometric measurements

Body weight was measured with the patients barefoot and lightly clothed to the nearest 0.1 kg using calibrated digital scales (Seca, Germany ref. 224 1714009). The barefoot standing height was measured using a fixed stadiometer to the nearest 0.1 cm (Seca, Germany ref. 224 1714009). Following inclusion, the body mass index (BMI) of all participants was calculated using the following formula: body weight (Kg)/height (m²); obesity was defined as a BMI greater than the 95th percentile for sex and age based on The United States Centers for Disease Control and Prevention (CDC 2000).

2.3. Data Collection

The nutritional profiles of participants were established through food recall using a food model. The total daily intake of calories, carbohydrates, proteins, and fat were calculated.

2.4. Blood Analyses

Blood samples were collected in 5 cc aliquots from subjects using tubes containing EDTA. They were centrifuged and shipped to the Laboratory of the Institute of Tropical Disease, Universitas Airlangga for the analysis of inflammatory biomarkers, including hsCRP. Serum levels of hsCRP (ref. CAN-CRP-4360) were measured by specific ELISA kits (*Bioassay Technology Laboratory, China*) following the manufacturer's instructions.

2.5. Statistical Analysis

Data were analyzed using the SPSS software. The value of p<0.05 was taken as statistically significant. The Pearson correlation analysis was performed to examine the relationship between calories, protein, carbohydrate, fat, and hsCRP.

3. Results and Discussion

A total of 59 adolescents were included in this study, consisting of 32 (54.2%) males and 27 (45.8%) females. The age range was 13–16 years. Anthropometric measurements, dietary intake, and laboratory characteristics are shown in Table 1

Variable	Mean (SD)
Body weight (kg)	80.77 ± 13.35
Body height (cm)	158.76 ± 7.12
Body Mass Index (kg/m ²)	31.99 ± 3.67

 Table 1. Characteristics of subjects

Calories (Kcal/day)	1955.96 ± 778.01		
Carbohydrate (Kcal/day)	1005.95 ± 421.67		
Protein (Kcal/day)	361.66 ± 221.43		
Fat (Kcal/day)	589.03 ± 313.25		
hsCRP (ng/ml)	2308.83 (285.79–2941.37)		

The mean hsCRP level was 2308.83 ± 470.95 ng/ml. The mean calorie intake was 1955.96 ± 778 calories. The correlation between dietary intake and hsCRP is given in Table 2.

Table 2. Correlation between dietary intake and inflammatory				y biomarkers
Variable	Total	Carbohydrate	Protein	Fat
	Calories			
hsCRP				
r	-0.167	-0.178	-0.015	-0.164
р	0.207	0.177	0.910	0.215

Table 2. Correlation between dietary intake and inflammatory biomarkers

In this study, there were no significant correlations between total calories, carbohydrate, protein, and fat level intake and hsCRP (p>0.05) (Table 2.).

Obesity is associated with oxidative stress and aseptic inflammation (Paltoglou et al., 2017). This inflammation is associated with the development of many comorbidities, including metabolic syndrome, cardiovascular disease (CVD) and type 2 diabetes (DeBoer, 2013). Fat cell size and fat cell number are increased in obesity or with a combination of the two (Coelho et al., 2013). Adipose tissue is an endocrine organ secreting adipocytokines, which exert endocrine, paracrine, and autocrine actions, both locally and systemically (Kelishadi et al., 2017). There is an increase in the adipocyte number (hyperplasia) and adipocyte size (hypertrophy), which releases various cytokines such as leptin, adiponectin, tumor necrosis factor-alpha (TNF-α), interleukin (IL)-1, IL-4, IL-6, IL-10, and CRP (Castro et al., 2017). These cytokines induce oxidative stress and inflammation (Ellulu et al., 2017). Elevated inflammatory biomarkers were higher in abdominal adiposity (Steckhan et al., 2016).

HsCRP and TNF- α were significantly higher in obese compare to non-obese individuals (Ayoub et al., 2015). HsCRP is an acute phase protein produced by the liver. HsCRP is negatively associated with anti-oxidation in prepubertal obese boys (Paltoglou et al., 2017). In inflammatory conditions, hsCRP plasma levels are increased and associated with metabolic syndrome, insulin resistance, and cardiovascular disease (DeBoer, 2013). TNF- α is a proinflammatory cytokine produced bv macrophages and T lymphocytes (Kelishadi et al., 2017). Elevated TNF- α is associated with insulin resistance and cardiovascular risk (Khosravi et al., 2013). Higher BMI is associated with a higher TG/HDL ratio and insulin resistance in pre- and post-pubertal children (Olson et al., 2012).

Dietary imbalances characterized by an excessive intake of calories, fat, and carbohydrate are observed in obese subjects (Ayoub et al., 2015). High fat and energy-dense foods are a dietary habit in obesity (Manna and Jain, 2015). The excessive fat and carbohydrate is associated with inflammation (Ayoub et al., 2015). Polyunsaturated acids, fatty an appropriate glycemic index and glycemic load in carbohydrates are associated with improving inflammation in obesity (Lee et al., 2013). Dietary fatty acids influence the expression of the TNF- α cytokine gene and alter TNF- α production (Joffe et al., 2013). The excessive

intake of carbohydrate and fat is associated with increased TNF- α (Ayoub et al., 2015).

A high protein diet did not improve anthropometric measurements and cardiovascular risk factors (LDL, HDL, insulin, and blood pressure) in obese children (Izadi et al., 2018). However, the energy-restricted high protein diet is associated with a reduction of waist circumference and hsCRP in women (Azadbakht et al., 2013). A low fat diet can reduce CRP (Steckhan et al., 2016).

In this study, no correlation was found between calories, carbohydrate, protein, fat level intake and hsCRP (Figure 1-4.). There was ethnicity difference with another study that showed correlation between dietary intake and inflammatory biomarkers.

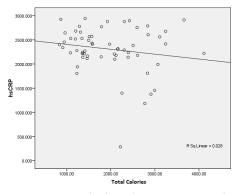

Figure 1. Correlation between Total Calories and hsCRP.

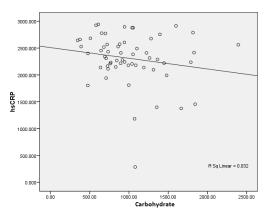

Figure 2. Correlation between Carbohydrate and hsCRP.

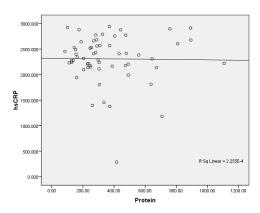

Figure 3. Correlation between Protein and hsCRP.

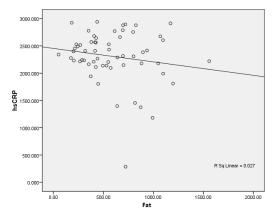

Figure 4. Correlation between Fat and hsCRP.

Dairy product consumption does not influence the biomarkers of inflammation (Labonté et al., 2013). Recent studies in the literature have reported that dietary intake has a positive effect on inflammatory biomarkers in patients with metabolic syndrome (Steckhan et al., 2016). The metabolic syndrome was not examined in this study.

There are limitations on this study. First, the sample size was small. Second, the study only obtained 24 hour recalls once. Third, there was a factor affecting of hsCRP, such as physical activity.

4. Conclusions

No effect of dietary intake of calories, carbohydrate, fat, and protein was found for hsCRP. Further studies are needed with larger sample sizes to investigate dietary food composition and its influence on inflammatory biomarkers in adolescents with obesity.
