Title: The Comparison of Pleural Fluid TNF-α Levels in Tuberculous and Nontuberculous Pleural Effusion
Journal: Indian Journal of Tuberculosis

Dear Dr. Yudhawati,

Thank you for submitting your manuscript for consideration for publication in Indian Journal of Tuberculosis. Your submission was received in good order.

To track the status of your manuscript, please log into EVISE® at: http://www.evise.com/evise/faces/pages/navigation/NavController.jspx?JRNL_ACR=IJTB and locate your submission under the header 'My Submissions with Journal' on your 'My Author Tasks' view.

Thank you for submitting your work to this journal.

Kind regards,

Indian Journal of Tuberculosis

Title: The Comparison of Pleural Fluid TNF-α Levels in Tuberculous and Nontuberculous Pleural Effusion
Journal: Indian Journal of Tuberculosis

Dear Dr. Yudhawati,

I am currently identifying and contacting reviewers who are acknowledged experts in the field. Since peer review is a voluntary service it can take time to find reviewers who are both qualified and available. While reviewers are being contacted, the status of your manuscript will appear in EVISE® as 'Reviewer Invited'.

Once a reviewer agrees to review your manuscript, the status will change to 'Under Review'. When I have received the required number of expert reviews, the status will change to 'Ready for Decision' while I evaluate the reviews before making a decision on your manuscript.

To track the status of your manuscript, please log into EVISE® and go to 'My Submissions' via:
http://www.evise.com/evise/faces/pages/navigation/NavController.jspx?JRNL_ACR=IJTB

Kind regards,

Indian Journal of Tuberculosis

Journal: Indian Journal of Tuberculosis

Dear Dr. Yudhawati,

I am pleased to inform you that your paper has been accepted for publication. My own comments as well as any reviewer comments are appended to the end of this letter. Now that your manuscript has been accepted for publication it will proceed to copy-editing and production.

Thank you for submitting your work to Indian Journal of Tuberculosis. We hope you consider us again for future submissions.

Kind regards,

Vijay Arora
Executive Editor
Indian Journal of Tuberculosis

Comments from the editors and reviewers:
- Reviewer 1

- The article adds to medical literature regarding role of pleural fluid biomarkers in tubercular pleural effusions and also furthers knowledge regarding pathogenesis.Hence it may be accepted for publication

P-authorproof-v8a

Dear Author

The proof of your article, to be published in INDIAN JOURNAL OF TUBERCULOSIS, is attached to this e-mail as a 'PDF' file. Also attached are instructions on the annotation of PDF files. You may also have a 'Query Form' as an attachment if we have any questions regarding your article.

Please note that proof corrections can now be annotated on-screen, which allows you to mark directly in the PDF file, and return the marked file as an e-mail attachment. To take advantage of this method, please download the free Adobe Reader version 7 (or higher; see the attached instructions).

Alternative methods of returning proof corrections:
If you do not wish to use the PDF annotations function, you may list the corrections (including replies to the Query Form) in an e-mail and return them to us using the 'reply' button to this e-mail. Please list your corrections quoting line number.

If, for any reason, this is not possible, mark the corrections and any other comments (including replies to the Query Form) on a printout of your proof and fax this to the number given below, or scan the pages and return them by e-mail.

We prefer to receive your corrections by e-mail or fax so that we can process your article quickly and efficiently. However, if you wish to return your corrections by post then please contact us and we will provide the full postal address.

Please use this proof for checking the typesetting, editing, completeness and correctness of the text, tables and figures. Please ensure that you answer any questions (see the Query Form) that have arisen during the preparation of your proof. Significant changes to the article as accepted for publication will only be considered at this stage with permission from the Editor. We will do everything possible to get your article published quickly and accurately. Therefore, it is important to ensure that all of your corrections are sent back to us in one communication: please check carefully before replying, as inclusion of any subsequent corrections cannot be guaranteed.

If you submitted usable colour figures with your article they will appear in colour on the web, at no extra charge, as you can see in the attached PDF proof of your article. In the printed issue, colour reproduction depends on journal policy and whether or not you agree to bear any costs (not applicable to journals which appear only online). Any 'supplementary' material to your article (i.e., not appearing in print) will be accessible after your corrected article is placed online; such material is not part of the proofing procedure and is therefore not attached here.

Please respond promptly (even if you have no corrections): the sooner we hear from you, the sooner your corrected article will appear online. Note that Elsevier may proceed with publication of your article if no response is received.

Kind regards,

Elsevier

AUTHOR QUERY FORM

ELSEVIER	**Journal:** IJTB **Article Number:** 279	**Please e-mail your responses and any corrections to:** **E-mail:** corrections.esch@elsevier.thomsondigital.com

Dear Author,

Please check your proof carefully and mark all corrections at the appropriate place in the proof (e.g., by using on-screen annotation in the PDF file) or compile them in a separate list. Note: if you opt to annotate the file with software other than Adobe Reader then please also highlight the appropriate place in the PDF file. To ensure fast publication of your paper please return your corrections within 48 hours.

For correction or revision of any artwork, please consult http://www.elsevier.com/artworkinstructions.

Any queries or remarks that have arisen during the processing of your manuscript are listed below and highlighted by flags in the proof. Click on the 'Q' link to go to the location in the proof.

Location in article	Query / Remark: click on the Q link to go Please insert your reply or correction at the corresponding line in the proof
Q1	The author names have been tagged as given names and surnames (surnames are highlighted in teal color). Please confirm if they have been identified correctly.
Q2	"Your article is registered as a regular item and is being processed for inclusion in a regular issue of the journal. If this is NOT correct and your article belongs to a Special Issue/Collection please contact s.bodatte@elsevier.com immediately prior to returning your corrections.".
Q3	Please check the placement of Fig. 1 and Tables 1-8, and correct if necessary.
	Please check this box or indicate your approval if you have no corrections to make to the PDF file ☐

Thank you for your assistance.

TB pleural fluid
Non-TB pleural fluid
TNF-α pleural fluid level
Mycobacterium tuberculosis

ABSTRACT

Background: Tuberculous pleural effusion is the manifestation of Mycobacterium tuberculosis infection in pleura with the total of ±31%. With existing means, it is difficult to establish the diagnosis of tuberculosis (TB) and non-TB pleural effusions; thus, establishing the diagnosis of TB pleural effusion and non-TB pleural effusion is still a clinical problem. The study of Ambade on differential diagnostic markers for both TB and non-TB pleural effusions had significantly higher levels of TNF-α pleural fluid in the TB pleural effusion group compared with the non-TB pleural effusion group.
Objective: To compare the TNF-α level of pleural fluid in TB and non-TB pleural effusion.
Methods: The samples in this study that fulfilled the inclusion criteria were patients with non-TB pleural tuberculosis effusion in the inpatient ward in Pulmonology Unit Dr. Soetomo General Hospital Surabaya, male and female, aged between 15 and 60 years. The data is divided intro two: primary data and secondary data of patients who fulfilled inclusion and exclusion criteria. The data with normal distribution was processed using independent *t*2 test and if the data distribution is abnormal, it was analyzed using Fisher's exact test.
Results: There were 22 subjects divided into 2 groups that were 11 patients with TB pleural effusion and 11 patients with non-TB pleural effusion. The TNF-α level of pleural fluid in TB pleural effusion was 25.43 ± 13.55 pg/mL. The TNF-α level of pleural fluid in non-TB was 5.98 ± 1.89 pg/mL. The serum TNF-α level in TB pleural effusion was 83.22 ± 88.15 pg/mL. The serum TNF-α level in non-TB was 68.54 ± 57.88 pg/mL. There was higher level of TNF-α pleural fluid in TB pleural effusion than in non-TB pleural effusion (25.43 ± 13.55 pg/mL vs 5.98 ± 1.89 pg/mL, *p* value of 0.001 <0.05). The serum TNF-α level in patients with TB pleural effusion was higher than TNF-α serum level of non-TB pleural effusion. There was no significant difference between TNF-α level of pleural fluid and serum TNF-α levels in the TB pleural effusion group (*p* value 0.073 >0.05).
Conclusion: The TNF-α level of pleural fluid in TB pleural effusion was higher than non-TB pleural effusions and there was no significant difference between serum TNF-α levels in the TB pleural effusion group and in the non-TB pleural effusion group.

1. Introduction

Tuberculosis (TB) is an infectious disease caused by Mycobacterium tuberculosis and is a major cause of morbidity and mortality in developing countries. Indonesia is on the fourth rank after India, Africa and China. Pleural effusion in TB is a manifestation of Mycobacterium tuberculosis infection in the pleura with an incidence rate of approximately ±31%.[1,2] Medical record data in lung treatment room of dr. Soetomo General Hospital Surabaya in 2012 found 37 patients with TB pleural effusion per year while there were 39 patients in 2013. The golden standard of TB pleural effusion is a conventional test in discovering Mycobacterium tuberculosis. Conventional methods such as acid resistant bacteria pleural fluid, pleural fluid culture, acid resistant bacteria sputum smear, acid resistant bacteria sputum culture and pleural fluid analysis are often found to be negative due to the small number of germs. On the other hand, the right and effective diagnosis is important in controlling the disease. Given the process of hypersensitivity reactions in TB, there are some biomarkers for diagnostic testing of TB pleural effusion, such as examining IFN levels of gamma in pleural fluid.[3]

Cytokines in TB pleural effusions are derived from Th1 cells TNF-α, which acts as a major inflammatory mediator in local reactions in the pleura for formation of granulomas. The mycobacteria antigen in the pleura interacts with T cells which is previously sensitized by mycobacteria. This will trigger a slow type of hypersensitivity reaction and cause a caseous necrosis of granuloma which will subsequently affect the pleural capillary permeability towards the protein resulting in pleural effusion.[4]

TB pleura effusion is an exudative pleural effusion mostly caused by Mycobacterium tuberculosis. With existing means, it is difficult to establish the diagnosis of TB and non-TB pleural effusions; thus, establishing the diagnosis of TB pleural effusion and non-TB pleural effusion is still a clinical problem. The study of Ambade on differential diagnostic markers for both TB and non-TB pleural effusions had significantly higher levels of TNF-α pleural fluid in the TB pleural effusion group compared with the non-TB pleural effusion group.[5]

In Indonesia, research on the level of TNF-α pleural fluid in TB pleural effusions has not been undergone; therefore, the researchers are intended in conducting the comparison the TNF-α levels of pleural fluid in TB and non-TB pleural effusion.

2. Methods

This research was cross sectional analytic observational study. The samples in this study that fulfilled the inclusion criteria were patients with TB and non-TB pleural tuberculosis effusion in the inpatient ward in Pulmonology Unit Dr. Soetomo General Hospital Surabaya, male and female, aged between 15 and 60 years, and signed the informed consent.

The variables were divided into independent and dependent variable in which the independent variable was TNF-α level of pleural fluid while the dependent variable was the pleural effusion of TB and non-TB. The TNF-α level of pleural fluid and TNF-α were examined with human TNF alpha ELISA kit.

The samples were undergone pleural fluid aspiration and collected their venous blood. It was examined the TNF-α of pleural fluid and peripheral blood serum. The examination began with collecting 3 cc of pleural fluid began, then put in a tube and stored in a refrigerator with a temperature of −70 °C. The measurement of TNF-α level was performed using ELISA kit by centrifuging the pleural fluid sample for 20 min. The supernatant obtained was added to TNF-α reagent. In examining the serum, venous blood was taken as much as 3 cc; then, it was centrifuged for several minutes. It was put in a tube and stored in a refrigerator with a temperature of −70 °C. Afterwards, the examination of TNF-α level was measured by ELISA kit by adding TNF-α reagent in patients' serum.

The data is divided into two: primary data and secondary data of patients who fulfilled inclusion and exclusion criteria. The data with normal distribution was processed using independent t2 test and if the data distribution is abnormal, it was analyzed using Fisher's exact test.[6,7]

3. Results

In the TB pleural effusion group, there were 7 (63.6%) male and 4 (36.4%) female patients. In the non-TB pleural effusion group, there were 5 (45.5%) male and 6 (54.5%) female patients. The result of Chi-square test showed that there was no significant difference of sex proportion between TB pleural group and non-TB pleural effusion group with p value of 0.392 >0.05. The mean age in the TB pleural treatment group was 27.0 years old, with the youngest age of 16 and the oldest age of 40 years old. The most age group was 16–25 years old that were 5 (45.5%) patients. The mean age in the non-TB pleural treatment group was 61.3 years old, with the youngest age of 47 years old and the oldest age of the oldest 78 years old. The most age group was 46–55 years old that were 4 (36.4%) patients (Figs. 1 and 2). Q3 The independent t-test results showed that there was a significant difference between the age group in TB pleural effusion and the age group in non-TB pleural effusion with p value of 0.000 <0.05. The TB pleural effusion group had a younger age than the non-TB pleural effusion group.

The normality included the age data, TNF-α pleural fluid level and serum TNF-α level were examined by using Kolmogorov Smirnov test. It was obtained that the age data, TNF-α level of pleural fluid and serum TNF-α level were normally distributed with $p > 0.05$. The result of Chi-square test between gender and TNF-α level of pleural fluid in the TB and non-TB pleural effusion group concluded that there was no significant association between gender and TNF-α level of pleural fluid with $p > 0.05$. It can be concluded that gender was not associated with high levels of TNF-α pleural fluid. The result of Pearson correlation test between age and TNF-α level of pleural fluid in TB and non-TB pleural effusion group showed that there was no significant association between age and TNF-α fluid level with $p > 0.05$. It can be concluded that age was not associated with high levels of TNF-α fluid pleura. The result of Chi-square test between gender and TNF-α serum level in the TB and non-TB pleural effusion group showed that there was no significant association between gender and TNF-α serum level $p > 0.05$. It can be concluded that gender was not

Please cite this article in press as: Damayanti N, Yudhawati R. The comparison of pleural fluid TNF-α levels in tuberculous and nontuberculous pleural effusion, *Indian J Tuberc.* (2018), https://doi.org/10.1016/j.ijtb.2018.05.017

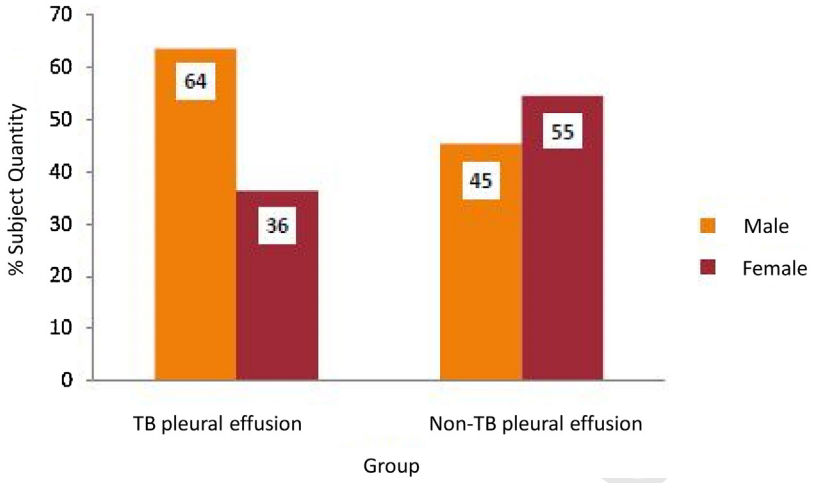

Fig. 1 – The characteristics of research subjects based on gender.

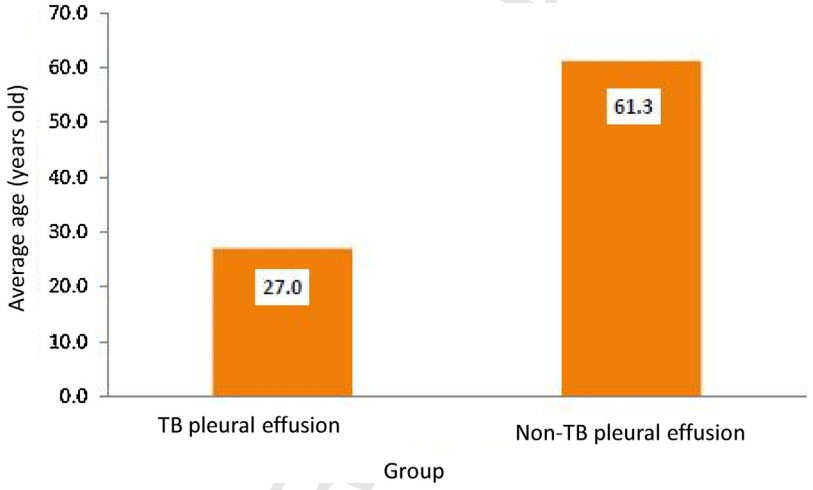

Fig. 2 – The characteristics of research subjects based on age.

associated with high levels of TNF-α serum. The result of Pearson correlation test between age and TNF-α serum level in TB and non-TB pleural effusion group showed that there was no significant association between age and TNF-α serum level with $p > 0.05$. It can be concluded that age was not associated with high levels of TNF-α serum.

The mean TNF-α level of pleural fluid in the TB pleural group was 25.43 pg/mL, with the lowest levels of 11.17 pg/mL and the highest level of 55.12 pg/mL. On the other hand, the mean TNF-α level of pleural fluid in the non-TB pleural effusion group was 5.98 pg/mL, with the lowest level of 3.35 pg/mL and the highest level of 10.20 pg/mL. The independent t test results showed that there was a significant difference between TNF-α level of pleural fluid in TB and non-TB pleural effusion group with p value of 0.001 <0.05 (Fig. 3). It was concluded that TNF-α levels of pleural fluid were higher in TB pleural effusion than in non-TB pleural effusion. The mean TNF-α serum level in TB pleural effusion group was 83.22 pg/mL, with the lowest level of 12.62 pg/mL and the highest level of 259.69 pg/mL. On the other hand, the mean TNF-α serum level in the non-TB pleural effusion group was 68.54 pg/mL, with the lowest level of 13.08 pg/mL and the highest level of 203.80 pg/mL. The independent t test results showed that there was no significant difference between TNF-α serum level in TB and non-TB pleural effusion group with p value of 0.649 >0.05 (Fig. 4). In the TB pleural effusion group, the mean TNF-α pleural fluid level was 25.43 pg/mL, with the lowest levels of 11.17 pg/mL and the highest level of 55.12 pg/mL. On the other hand, the mean TNF-α serum level was 83.22 pg/mL, with the lowest level of 12.62 pg/mL and the highest level of 259.69 pg/mL. The result of paired t test showed that there was no significant difference between TNF-α level of pleural fluid and TNF-α serum level in the TB pleural effusion group with p value of 0.073 >0.05 (Fig. 5).

In the non-TB pleural effusion group, the average TNF-α pleural fluid level of 5.98 pg/mL, with the lowest level of 3.35 pg/mL and the highest level of 10.20 pg/mL. On the other hand, the mean TNF-α serum level was 68.54 pg/mL, with the

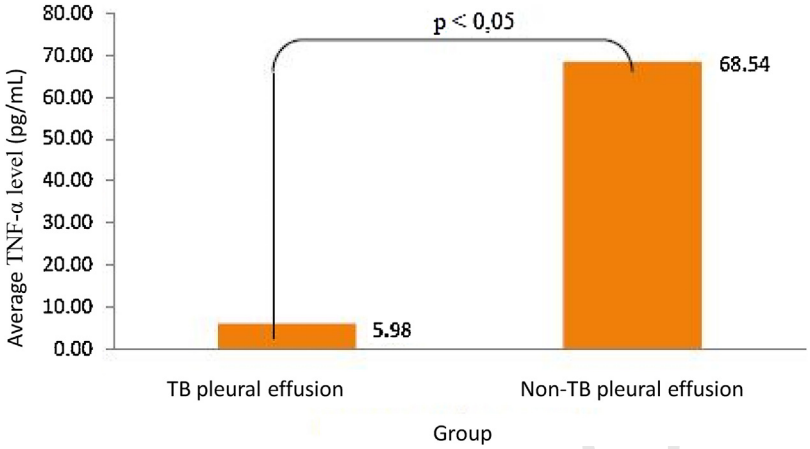

Fig. 6 – The comparison of TNF-α pleural fluid level and TNF-α serum level between non-TB pleural effusion group.

lowest level of 13.08 pg/mL and the highest level of 203.80 pg/mL. The result of paired *t* test showed that there was a significant difference between TNF-α level of pleural fluid and TNF-α serum level in the non-TB pleural effusion group with *p* value of 0.005 <0.05. The TNF-α serum level was higher than TNF-α level of pleural fluid (Fig. 6).

4. Discussion

There were 22 subjects divided into 2 groups that were 11 patients with TB pleural effusion and 11 patients with non-TB pleural effusion. In the TB pleural effusion group, there were 7 (63.6%) male and 4 (36.4%) female patients. In the non-TB pleural effusion group, there were 5 (45.5%) male and 6 (54.5%) female patients. This is in accordance with WHO Global Tuberculosis Report in 2013 which is male to female ratio of 1.5:1.[1] The Chi-square test results concluded that there was no significant association between gender and TNF-α level of pleural fluid with $p > 0.05$. This means gender is not associated with high levels of TNF-α pleural fluid.

The age characteristic in the TB pleural effusion group was 27.0 years old, with the youngest age of 16 years old and the oldest age of 40 years old. The most age group is 16–25 years old that is 5 (45.5%) patients. The mean age in the non-TB pleural treatment group was 61.3 years old, with the youngest age of 47 years old and the oldest age of 78 years old. The most age group was 46–55 years old that were 4 (36.4%) patients. The independent t test results showed that there was a significant difference between the age group in TB pleural effusion and the age group in non-TB pleural effusion with *p* value of 0.000 <0.05. Pearson correlation results concluded that there was no significant association between age and TNF-α level of pleural fluid with $p > 0.05$. It can be concluded that age is not associated with high levels of TNF-α fluid pleural. The TB pleural effusion group had a younger age than the non-TB pleural effusion group, according to a study conducted in Korea in 2012 that reported TB disease occurred in the productive age group between 15 and 49 years old.[8] It indicates that the susceptible age group to TB is the productive age group and males are more susceptible than females.[1,8] The result of the normality test by using Kolmogorov Smirnov test showed that the data was normally distributed.

In this study, the mean TNF-α fluid effusion in the TB pleural effusion group of 25.43 pg/mL, with the lowest levels of 11.17 pg/mL and the highest levels of 55.12 pg/mL. Yamada et al. obtained TNF-α levels in pleural fluid of 37.8 ± 11.7 pg/mL. Tahhan et al. obtained TNF-α level of pleural fluid at 65.4 ± 136.9 pg/mL whereas Ambade et al., on TB and non-TB pleural effusion obtained TNF-α level of 195.5 ± 292.1 pg/mL.[5,9,10] The mean TNF-α pleural fluid in the non-TB pleural effusion group was 5.98 pg/mL, with the lowest level of 3.35 pg/mL and the highest level of 10.20 pg/mL. It shows a major protective immune response mediated by local CMI by macrophages that work with Th1 lymphocytes. The Th1 lymphocyte complex with specific antigen of Mycobacterium tuberculosis presented in the pleural cavity through IL-12 will trigger the secretion of cytokines from Th1 cells including TNF-α.[11] The assessment of TNF-α level of TB pleural fluid effusion indicates its role in the body's defense mechanisms towards granuloma-forming reactions, elimination of intramacrophage bacillary antigens, and fibrosis to stop TB.[12,13] The study examined experimental rats, in which rats with deficiency of this receptor would be more susceptible to the occurrence of Mycobacterium tuberculosis infection. This is due to the inability of macrophages to produce TNF-α.[14]

The mean TNF-α serum level in the TB pleural effusion group was 83.22 pg/mL, with the lowest level of 12.62 pg/mL and the highest level of 259.69 pg/mL. On the other hand, the mean TNF-α serum level in the non-TB pleural effusion group was 68.54 pg/mL, with the lowest level of 13.08 pg/mL and the highest level of 203.80 pg/mL. The independent *t* test results showed that there was no significant difference between TNF-α serum level in TB and non-TB pleural effusion group with *p* value of 0.649 >0.05.

Tahhan et al. obtained TNF-α serum level of 2.55 ± 5.23 pg/mL which is lower than the result of this study.[10] However, it is similar to the study conducted by Andrate et al. that obtained higher TNF-α serum level than the level of TNF-α pleural fluid. TNF-α serum levels were 9055.6 pg/mL, 1519.9 pg/mL and

Please cite this article in press as: Damayanti N, Yudhawati R. The comparison of pleural fluid TNF-α levels in tuberculous and nontuberculous pleural effusion, *Indian J Tuberc.* (2018), https://doi.org/10.1016/j.ijtb.2018.05.017

2848.0 pg/mL affected by the clinical severity of Mycobacterium tuberculosis.[15]

The mean TNF-α level of pleural fluid in the TB pleural group was 25.43 pg/mL, with the lowest levels of 11.17 pg/mL and the highest level of 55.12 pg/mL. On the other hand, the mean TNF-α level of pleural fluid in the non-TB pleural effusion group was 5.98 pg/mL, with the lowest levels of 3.35 pg/mL and the highest levels of 10.20 pg/mL. The independent t test results showed that there was a significant difference between TNF-α level of pleural fluid in TB and non-TB pleural effusion group with p value of 0.001 <0.05 (25.43 ± 13.55 pg/mL vs 5.98 ± 1.89 pg/mL). It is in accordance with a research conducted by Tahhan et al. that higher TNF-α level of pleural fluid than the serum level (65.4 ± 136.9 pg/mL vs 54.5 ± 144.2 pg/mL; $p < 0.001$) while Ambade et al., obtained higher TNF-α level in TB group than non-TB group (195.5 ± 292.1 pg/mL vs 59.7 ± 128.9 pg/mL; $p < 0.01$).[5,10] It can be concluded that TNF-α level of pleural fluid is higher in TB pleural effusion than in non-TB pleural effusion group.

In this study, four patients with pleural effusion in pneumonia had TNF-α level of 6.74 pg/mL, 4 pg/mL, 5.87 pg/mL and 5.45 pg/mL. It is considered lower compared to TNF-α level of pleural effusion in TB pleural effusion. The previous study conducted by Yamada et al. found that the level of TNF-α in TB pleural effusion was higher than TNF-α in pleural effusion caused by inflammation (9.2 ± 2.3 pg/mL vs 37.8 ± 11.7 pg/mL).[9] They also attained lower TNF-α level in malignant pleural effusion of 6.3 ± 0.7 pg/mL than in TB pleural effusion (37.8 ± 11.7 pg/mL).[9] Among 11 patients with non-TB pleural effusion in this study, seventeen of whom were patients with malignant pleural effusion. TNF-α level of pleural fluid was also found to be lower than the mean level of TNF-α pleural fluid in TB. Lie et al. obtained higher TNF-α level of pleural fluid (45.55 ± 15.58 pg/m/L) than TNF-α level in malignant pleural effusion (17.18 ± 4.84 pg/mL).[16] Ambade et al. also obtained the mean TNF-α level in TB pleural effusion of 195.5 pg/mL, TNF-α level of pleural effusion because by pneumonia of 55 pg/mL and TNF-α level in malignant pleural effusion of 61 pg/mL.[5]

In the TB pleural effusion group, the mean TNF-α pleural fluid level was 25.43 pg/mL, with the lowest levels of 11.17 pg/mL and the highest level of 55.12 pg/mL. On the other hand, the mean TNF-α serum level was 83.22 pg/mL, with the lowest level of 12.62 pg/mL and the highest level of 259.69 pg/mL. The result of paired t test showed that there was no significant difference between TNF-α level of pleural fluid and TNF-α serum level in the TB pleural effusion group with p value of 0.073 >0.05 (25.4 ± 13.55 pg/mL vs 83.22 ± 88.15 pg/mL; p 0.073).

In the non-TB pleural effusion group, the average TNF-α pleural fluid level of 5.98 pg/mL, with the lowest level of 3.35 pg/mL and the highest level of 10.20 pg/mL. On the other hand, the mean TNF-α serum level was 68.54 pg/mL, with the lowest level of 13.08 pg/mL and the highest level of 203.80 pg/mL. The result of paired t test showed that there was a significant difference between TNF-α level of pleural fluid and TNF-α serum level in the non-TB pleural effusion group with p value of 0.005 <0.05 (5.98 ± 1.89 pg/mL vs 68.54 ± 57.88 pg/mL). The TNF-α serum level was higher than TNF-α level of pleural fluid.

The high concentration of cytokines in pleural fluid reflects local immune stimulation. It occurs because of the migration of T cells from the periphery to the site of the disease. Thus, TNF-α cytokines are secreted at the site of the disease to increase the level of TNF-α cytokine in pleural effusion than TNF-α level in plasma.[17,18] This study obtained different results with Prabha et al.'s research on 46 patients with TB pleural effusion encountered increased level of TNF-α significantly than the level in plasma.[19] The role of TNF-α as proinflammatory cytokines that have immunoprotective role to control the growth of Mycobacterium tuberculosis as well as the detrimental role in immunopathology of TB. In patients with weight loss, TNF-α serum levels are elevated; thus, this mediator is presumed to play an important role in cortex.

Andrate et al. in his study regarding the association between TNF-α level and clinical TB severity was found that patients with lower body weight had higher serum TNF-α level (15,468.54 ± 4580.54 pg/mL) than patients without weight loss (2904.98

Table 2 – The normality data of age, TNF-α level of pleural fluid and TNF-α serum level.

Data	p value	
	TB pleural effusion	Non-TB pleural effusion
Age (years old)	0.995	0.996
TNF-α level of pleural fluid (pg/mL)	0.884	0.932
TNF-α serum level (pg/mL)	0.601	0.912

Table 1 – The characteristics of research subjects.

± 1367.89 pg/mL) with *p* value of <0.05. This suggests that, besides being caused by virulence levels, it is also caused by the effect of TB pathogenesis that is affected by clinical severity marked by weight loss conditions.[2,4] Andrate et al.'s research obtained the association between BB with high TNF-α serum level. Patients with a low weight obtained higher TNF-α serum level than patients without decreased weight (Tables 1–8).

Mycobacterium tuberculosis

ABSTRACT

Background: Tuberculous pleural effusion is the manifestation of Mycobacterium tuberculosis infection in pleura ~~with the total of ±31%~~. With existing means, it is difficult to establish the diagnosis of tuberculosis (TB) and non-TB pleural effusions; thus, establishing the diagnosis of TB pleural effusion and non-TB pleural effusion is still a clinical problem. ~~The study of Ambade on differential diagnostic markers for both TB and non-TB pleural effusions had significantly higher levels of TNF-α pleural fluid in the TB pleural effusion group compared with the non-TB pleural effusion group.~~

Objective: To compare the TNF-α level of pleural fluid in TB and non-TB pleural effusion.

Methods: The samples in this study that fulfilled the inclusion criteria were patients with non-TB pleural tuberculosis effusion in the inpatient ward in Pulmonology Unit Dr. Soetomo General Hospital Surabaya, male and female, aged between 15 and 60 years. The data is divided into two: primary data and secondary data of patients who fulfilled inclusion and exclusion criteria. The data with normal distribution was ~~processed~~ using independent *t*2 test and if the data distribution is abnormal, it was analyzed using Fisher's exact test.

Results: There were 22 subjects divided into 2 groups that were 11 patients with TB pleural effusion and 11 patients with non-TB pleural effusion. The TNF-α level of pleural fluid in TB pleural effusion was 25.43 ± 13.55 pg/mL. The TNF-α level of pleural fluid in non-TB was 5.98 ± 1.89 pg/mL. The serum TNF-α level in TB pleural effusion was 83.22 ± 88.15 pg/mL. The serum TNF-α level in non-TB was 68.54 ± 57.88 pg/mL. There was higher level of TNF-α pleural fluid in TB pleural effusion than in non-TB pleural effusion (25.43 ± 13.55 pg/mL vs 5.98 ± 1.89 pg/mL, *p* value ~~of 0.001~~ <0.05). The serum TNF-α level in patients with TB pleural effusion was higher than TNF-α serum level of non-TB pleural effusion. There was no significant difference between TNF-α level of pleural fluid and serum TNF-α levels in the TB pleural effusion group (*p* value ~~0.073~~ >0.05).

Conclusion: The TNF-α level of pleural fluid in TB pleural effusion was higher than non-TB pleural effusions and there was no significant difference between serum TNF-α levels in the TB pleural effusion group and in the non-TB pleural effusion group.

1. Introduction

Q2 Tuberculosis (TB) is an infectious disease caused by Mycobacterium tuberculosis and is a major cause of morbidity and mortality in developing countries. Indonesia is on the fourth rank after India, Africa and China. Pleural effusion in TB is a manifestation of Mycobacterium tuberculosis infection in the pleura with an incidence rate of approximately ±31%.[1,2] Medical record data in ~~lung treatment room~~ of dr. Soetomo General Hospital Surabaya in 2012 found 37 patients with TB pleural effusion per year while there were 39 patients in 2013. The golden standard of TB pleural effusion is a conventional test in discovering Mycobacterium tuberculosis. Conventional methods such as acid ~~resistant bacteria pleural fluid, pleural fluid culture, acid resistant bacteria sputum smear, acid resistant bacteria sputum culture and pleural fluid analysis~~ are often found to be negative due to the small number of germs. On the other hand, the right and effective diagnosis is important in controlling the disease. Given the process of hypersensitivity reactions in TB, there are some biomarkers for diagnostic testing of TB pleural effusion, such as examining IFN ~~levels of gamma~~ in pleural fluid.[3]

~~Cytokines in TB pleural effusions are derived from Th1 cells TNF-α, which acts as a major inflammatory mediator in local reactions in the pleura for formation of granulomas.~~ The mycobacteria antigen in the pleura interacts with T cells which is previously sensitized by mycobacteria. This will trigger a ~~slow type of hypersensitivity reaction~~ and cause a caseous necrosis of granuloma which will subsequently affect the pleural capillary permeability towards the protein resulting in pleural effusion.[4]

TB pleura effusion is an exudative pleural effusion mostly caused by Mycobacterium tuberculosis. With existing means, it is difficult to establish the diagnosis of TB and non-TB pleural effusions; thus, establishing the diagnosis of TB pleural effusion and non-TB pleural effusion is still a clinical problem. ~~The study of Ambade~~ on differential diagnostic markers for both TB and non-TB pleural effusions had significantly higher levels of TNF-α pleural fluid in the TB pleural effusion group compared with the non-TB pleural effusion group.[5]

In Indonesia, research on the level of TNF-α pleural fluid in TB pleural effusions has not been ~~undergone~~; therefore, the researchers are intended in conducting the comparison the TNF-α levels of pleural fluid in TB and non-TB pleural effusion.

2. Methods

This research was cross sectional analytic observational study. The samples in this study that fulfilled the inclusion criteria were patients with TB and non-TB pleural tuberculosis effusion in the inpatient ward in Pulmonology Unit Dr. Soetomo General Hospital Surabaya, male and female, aged between 15 and 60 years, and signed the informed consent.

The variables were divided into independent and dependent variable in which the independent variable was TNF-α level of pleural fluid while the dependent variable was the pleural effusion of TB and non-TB. The TNF-α level of pleural fluid and TNF-α were examined with human TNF alpha ELISA kit.

The samples were undergone pleural fluid aspiration and collected their venous blood. It was examined the TNF-α of pleural fluid and peripheral blood serum. The examination began with collecting 3 cc of pleural fluid began, then put in a tube and stored in a refrigerator with a temperature of −70 °C. The measurement of TNF-α level was performed using ELISA kit by centrifuging the pleural fluid sample for 20 min. The supernatant obtained was added to TNF-α reagent. In examining the serum, venous blood was taken as much as 3 cc; then, it was centrifuged for several minutes. It was put in a tube and stored in a refrigerator with a temperature of −70 °C. Afterwards, the examination of TNF-α level was measured by ELISA kit by adding TNF-α reagent in patients' serum.

The data is divided into two: primary data and secondary data of patients who fulfilled inclusion and exclusion criteria. The data with normal distribution was ~~processed~~ using independent *t*2 test and if the data distribution is abnormal, it was analyzed using Fisher's exact test.[6,7]

3. Results

In the TB pleural effusion group, there were 7 (63.6%) male and 4 (36.4%) female patients. In the non-TB pleural effusion group, there were 5 (45.5%) male and 6 (54.5%) female patients. ~~The result of Chi-square test showed that there was no significant difference of sex proportion between TB pleural group and non-TB pleural effusion group with *p* value of 0.392 >0.05.~~ The mean age in the TB pleural treatment group was 27.~~0~~ years old, with the youngest age of 16 and the oldest age of 40 years old. The most age group was 16–25 years old that were 5 (45.5%) patients. The mean age in the non-TB pleural treatment group was 61.3 years old, with the youngest age of 47 years old and the oldest age of ~~the oldest~~ 78 years old. The most age group was 46–55 years old that were 4 (36.4%) patients (Figs. 1 and 2). Q3 The independent *t*-test results showed that there was a significant difference between the age group in TB pleural effusion and the age group in non-TB pleural effusion with *p* value ~~of 0.000~~ <0.05. The TB pleural effusion group had a younger age than the non-TB pleural effusion group.

The normality included the age data, TNF-α pleural fluid level and serum TNF-α level were examined by using Kolmogorov Smirnov test. It was obtained that the age data, TNF-α level of pleural fluid and serum TNF-α level were normally distributed with $p > 0.05$. The result of Chi-square test between gender and TNF-α level of pleural fluid in the TB and non-TB pleural effusion group concluded that there was no significant association between gender and TNF-α level of pleural fluid with $p > 0.05$. ~~It can be concluded that gender was not associated with high levels of TNF-α pleural fluid.~~ The result of Pearson correlation test between age and TNF-α level of pleural fluid in TB and non-TB pleural effusion group showed that there was no significant association between age and TNF-α fluid level with $p > 0.05$. ~~It can be concluded that age was not associated with high levels of TNF-α fluid pleura. The result of Chi-square test between gender and TNF-α serum level in the TB and non-TB pleural effusion group showed that there was no significant association between gender and TNF-α serum level *p* > 0.05. It can be concluded that gender was not~~

lowest level of 13.08 pg/mL and the highest level of 203.80 pg/mL. The result of paired t test showed that there was a significant difference between TNF-α level of pleural fluid and TNF-α serum level in the non-TB pleural effusion group with p value ~~of 0.005~~ <0.05. ~~The TNF-α serum level was higher than TNF-α level of pleural fluid~~ (Fig. 6).

4. Discussion

There were 22 subjects divided into 2 groups that were 11 patients with TB pleural effusion and 11 patients with non-TB pleural effusion. In the TB pleural effusion group, there were 7 (63.6%) male and 4 (36.4%) female patients. In the non-TB pleural effusion group, there were 5 (45.5%) male and 6 (54.5%) female patients. This is in accordance with WHO Global Tuberculosis Report in 2013 which is male to female ratio of 1.5:1.[1] The Chi-square test results concluded that there was no significant association between gender and TNF-α level of pleural fluid with $p > 0.05$. This means gender is not associated with high levels of TNF-α pleural fluid.

The age characteristic in the TB pleural effusion group was 27.0 years old, with the youngest age of 16 years old and the oldest age of 40 years old. The most age group is 16–25 years old that is 5 (45.5%) patients. The mean age in the non-TB pleural treatment group was 61.3 years old, with the youngest age of 47 years old and the oldest age of 78 years old. The most age group was 46–55 years old that were 4 (36.4%) patients. The independent t test results showed that there was a significant difference between the age group in TB pleural effusion and the age group in non-TB pleural effusion with p value ~~of 0.000~~ <0.05. Pearson correlation results concluded that there was no significant association between age and TNF-α level of pleural fluid with $p > 0.05$. It can be concluded that age is not associated with high levels of TNF-α fluid pleural. The TB pleural effusion group had a younger age than the non-TB pleural effusion group, according to a study conducted in Korea in 2012 that reported TB disease occurred in the productive age group between 15 and 49 years old.[8] It indicates that the susceptible age group to TB is the productive age group and males are more susceptible than females.[1,8] The result of the normality test by using Kolmogorov Smirnov test showed that the data was normally distributed.

In this study, the mean TNF-α fluid effusion in the TB pleural effusion group of 25.43 pg/mL, with the lowest levels of 11.17 pg/mL and the highest levels of 55.12 pg/mL. Yamada et al. obtained TNF-α levels in pleural fluid of 37.8 ± 11.7 pg/mL. Tahhan et al. obtained TNF-α level of pleural fluid at 65.4 ± 136.9 pg/mL whereas Ambade et al., on TB and non-TB pleural effusion obtained TNF-α level of 195.5 ± 292.1 pg/mL.[5,9,10] The mean TNF-α pleural fluid in the non-TB pleural effusion group was 5.98 pg/mL, with the lowest level of 3.35 pg/mL and the highest level of 10.20 pg/mL. It shows a major protective immune response mediated by local CMI by macrophages that work with Th1 lymphocytes. The Th1 lymphocyte complex with specific antigen of Mycobacterium tuberculosis presented in the pleural cavity through IL-12 will trigger the secretion of cytokines from Th1 cells including TNF-α.[11] The assessment of TNF-α level of TB pleural fluid effusion indicates its role in the body's defense mechanisms ~~towards granuloma-forming reactions, elimination of intramacrophage bacillary antigens, and fibrosis to stop TB~~.[12,13] The study examined experimental rats, in which rats with deficiency of this receptor would be more susceptible to the occurrence of Mycobacterium tuberculosis infection. This is due to the inability of macrophages to produce TNF-α.[14]

The mean TNF-α serum level in the TB pleural effusion group was 83.22 pg/mL, with the lowest level of 12.62 pg/mL and the highest level of 259.69 pg/mL. On the other hand, the mean TNF-α serum level in the non-TB pleural effusion group was 68.54 pg/mL, with the lowest level of 13.08 pg/mL and the highest level of 203.80 pg/mL. The independent t test results showed that there was no significant difference between TNF-α serum level in TB and non-TB pleural effusion group with p value ~~of 0.649~~ >0.05.

Tahhan et al. obtained TNF-α serum level of 2.55 ± 5.23 pg/mL which is lower than the result of this study.[10] However, it is similar to the study conducted by Andrate et al. that obtained higher TNF-α serum level than the level of TNF-α pleural fluid. TNF-α serum levels were 9055.6 pg/mL, 1519.9 pg/mL and

Please cite this article in press as: Damayanti N, Yudhawati R. The comparison of pleural fluid TNF-α levels in tuberculous and nontuberculous pleural effusion, *Indian J Tuberc.* (2018), https://doi.org/10.1016/j.ijtb.2018.05.017

2848.0 pg/mL affected by the clinical severity of Mycobacterium tuberculosis.[15]

The mean TNF-α level of pleural fluid in the TB pleural group was 25.43 pg/mL, with the lowest levels of 11.17 pg/mL and the highest level of 55.12 pg/mL. On the other hand, the mean TNF-α level of pleural fluid in the non-TB pleural effusion group was 5.98 pg/mL, with the lowest levels of 3.35 pg/mL and the highest levels of 10.20 pg/mL. The independent t test results showed that there was a significant difference between TNF-α level of pleural fluid in TB and non-TB pleural effusion group with p value ~~of 0.001~~ <0.05 (25.43 ± 13.55 pg/mL vs 5.98 ± 1.89 pg/mL). It is in accordance with a research conducted by Tahhan et al. that higher TNF-α level of pleural fluid than the serum level (65.4 ± 136.9 pg/mL vs 54.5 ± 144.2 pg/mL; $p < 0.001$) while Ambade et al., obtained higher TNF-α level in TB group than non-TB group (195.5 ± 292.1 pg/mL vs 59.7 ± 128.9 pg/mL; $p < 0.01$).[5,10] It can be concluded that TNF-α level of pleural fluid is higher in TB pleural effusion than in non-TB pleural effusion group.

In this study, four patients with pleural effusion in pneumonia had TNF-α level of 6.74 pg/mL, 4 pg/mL, 5.87 pg/mL and 5.45 pg/mL. It is considered lower compared to TNF-α level of pleural effusion in TB pleural effusion. The previous study conducted by Yamada et al. found that the level of TNF-α in TB pleural effusion was higher than TNF-α in pleural effusion caused by inflammation (9.2 ± 2.3 pg/mL vs 37.8 ± 11.7 pg/mL).[9] They also attained lower TNF-α level in malignant pleural effusion of 6.3 ± 0.7 pg/mL than in TB pleural effusion (37.8 ± 11.7 pg/mL).[9] Among 11 patients with non-TB pleural effusion in this study, seventeen of whom were patients with malignant pleural effusion. TNF-α level of pleural fluid was also found to be lower than the mean level of TNF-α pleural fluid in TB. Lie et al. obtained higher TNF-α level of pleural fluid (45.55 ± 15.58 pg/m/L) than TNF-α level in malignant pleural effusion (17.18 ± 4.84 pg/mL).[16] Ambade et al. also obtained the mean TNF-α level in TB pleural effusion of 195.5 pg/mL, TNF-α level of pleural effusion because by pneumonia of 55 pg/mL and TNF-α level in malignant pleural effusion of 61 pg/mL.[5]

In the TB pleural effusion group, the mean TNF-α pleural fluid level was 25.43 pg/mL, with the lowest levels of 11.17 pg/mL and the highest level of 55.12 pg/mL. On the other hand, the mean TNF-α serum level was 83.22 pg/mL, with the lowest level of 12.62 pg/mL and the highest level of 259.69 pg/mL. The result of paired t test showed that there was no significant difference between TNF-α level of pleural fluid and TNF-α serum level in the TB pleural effusion group with p value ~~of 0.073~~ >0.05 (25.4 ± 13.55 pg/mL vs 83.22 ± 88.15 pg/mL; ~~p 0.073~~).

In the non-TB pleural effusion group, the average TNF-α pleural fluid level of 5.98 pg/mL, with the lowest level of 3.35 pg/mL and the highest level of 10.20 pg/mL. On the other hand, the mean TNF-α serum level was 68.54 pg/mL, with the lowest level of 13.08 pg/mL and the highest level of 203.80 pg/mL. The result of paired t test showed that there was a significant difference between TNF-α level of pleural fluid and TNF-α serum level in the non-TB pleural effusion group with p value ~~of 0.005~~ <0.05 (5.98 ± 1.89 pg/mL vs 68.54 ± 57.88 pg/mL). The TNF-α serum level was higher than TNF-α level of pleural fluid.

The high concentration of cytokines in pleural fluid reflects local immune stimulation. It occurs because of the migration of T cells from the periphery to the site of the disease. Thus, TNF-α cytokines are secreted at the site of the disease to increase the level of TNF-α cytokine in pleural effusion than TNF-α level in plasma.[17,18] This study obtained different results with Prabha et al.'s research on 46 patients with TB pleural effusion encountered increased level of TNF-α significantly than the level in plasma.[19] The role of TNF-α as proinflammatory cytokines that have immunoprotective role to control the growth of Mycobacterium tuberculosis as well as the detrimental role in immunopathology of TB. In patients with weight loss, TNF-α serum levels are elevated; thus, this mediator is presumed to play an important role in cortex.

Andrate et al. in his study regarding the association between TNF-α level and clinical TB severity was found that patients with lower body weight had higher serum TNF-α level (15,468.54 ± 4580.54 pg/mL) than patients without weight loss (2904.98

Table 2 – The normality data of age, TNF-α level of pleural fluid and TNF-α serum level.

Data	p value	
	TB pleural effusion	Non-TB pleural effusion
Age (years old)	0.995	0.996
TNF-α level of pleural fluid (pg/mL)	0.884	0.932
TNF-α serum level (pg/mL)	0.601	0.912

Table 1 – The characteristics of research subjects.

Characteristics	Group		p
	TB pleural effusion	Non-TB pleural effusion	
Gender			
Male	7 (63.6%)	5 (45.5%)	0.392
Female	4 (36.4%)	6 (54.5%)	
Age (mean ± SD)	27.0 ± 7.6	61.3 ± 9.7	0.000
16–25 years old	5 (45.5%)	0 (0.0%)	
26–35 years old	4 (36.4%)	0 (0.0%)	
36–45 years old	2 (18.2%)	0 (0.0%)	
46–55 years old	0 (0.0%)	4 (36.4%)	
56–65 years old	0 (0.0%)	3 (27.3%)	
66–75 years old	0 (0.0%)	3 (27.3%)	
76–85 years old	0 (0.0%)	1 (9.1%)	

Please cite this article in press as: Damayanti N, Yudhawati R. The comparison of pleural fluid TNF-α levels in tuberculous and nontuberculous pleural effusion, *Indian J Tuberc.* (2018), https://doi.org/10.1016/j.ijtb.2018.05.017

± 1367.89 pg/mL) with *p* value of <0.05. This suggests that, besides being caused by virulence levels, it is also caused by the effect of TB pathogenesis that is affected by clinical severity marked by weight loss conditions.[2,4] Andrate et al.'s research obtained the association between BB with high TNF-α serum level. Patients with a low weight obtained higher TNF-α serum level than patients without decreased weight (Tables 1–8).

Table 3 – The association of gender and age with TNF-α level of pleural fluid.

TNF-α level of pleural fluid (pg/mL)		TB pleural effusion	Non-TB pleural effusion
Chi-square test	Gender	0.545	1.000
Pearson correlation	Age	0.967	0.393

Table 4 – The association of gender and age with TNF-α serum level.

TNF-α serum level (pg/mL)		TB pleural effusion	Non-TB pleural effusion
Chi-square test	Gender	0.576	1.000
Pearson correlation	Age	0.910	0.243

Table 5 – The Comparison of TNF-α level of pleural fluid between TB and non-TB pleural effusion group.

Group	TNF-α level of pleural fluid (pg/mL)	
	mean ± SD	*p* value
TB pleural effusion	25.43 ± 13.55	0.001
Non-TB pleural effusion	5.98 ± 1.89	

Table 6 – The comparison of TNF-α serum level between TB and non-TB pleural effusion group.

Group	TNF-α serum level (pg/mL)	
	mean ± SD	*p* value
TB pleural effusion	83.22 ± 88.15	0.649
Non-TB pleural effusion	68.54 ± 57.88	

Table 7 – The comparison of TNF-α level of pleural fluid and TNF-α serum level in TB pleural effusion group.

Variable	TB pleural effusion group	
	mean ± SD	*p* value
TNF-α level of pleural fluid	25.43 ± 13.55	0.073
TNF-α serum level	83.22 ± 88.15	

Table 8 – The comparison of TNF-α level of pleural fluid and TNF-α serum level in non-TB pleural effusion group.

Variable	Non-TB pleural effusion group	
	mean ± SD	*p* value
TNF-α level of pleural fluid	5.98 ± 1.89	0.005
TNF-α serum level	68.54 ± 57.88	

5. Conclusion

The level of TNF-α pleural fluid in TB pleural effusions were higher than in non-TB pleural effusions and there was no significant difference between TNF-α serum levels in TB and non-TB pleural effusion group.

ADVANCING WOMEN
Advancing women in science and libraries in the developing world:
Every year, the Elsevier Foundation provides grants to institutions around the world, with a focus on support for the world's libraries and for scholars in the early stages of their careers. Since 2002, The Elsevier Foundation has awarded more than 60 grants worth millions dollars to non-profit organizations focusing on helping the world's libraries, nurse faculties, and women scholars during their early and mid-careers. Maybe we can help you.
