 Department of Fish Health Management and Aquaculture, Faculty of Fisheries And Marine,
 Universitas Airlangga, Jl. Mulyorejo, Surabaya60113, East Java, Indonesia

*Coresponding author: kismiyati@fpk.unair.ac.id

Abstract. Milkfish (*Chanos chanos*) is a commodity that has the highest increase in consumption value, which is 24.55%. Milkfish production centers in Indonesia have developed such as in East Java, South Sulawesi, West Java, Central Java, and Southeast Sulawesi (DJPB, 2015). The technology of enlargement and seeding has been mastered and developed in the community, for example modular, semi-intensive and intensive systems. The difference in the growth of modular and semi-intensive milkfish systems has been observed in the Center for Brackish Water Aquaculture (BBPBAP) Jepara, Central Java on 19 December 2018 until 19 January 2019. Since 1 month, milkfish was observed with long, heavy growth parameters, life velocity of milkfish, and water quality. Milkfish enlargement techniques are preparation of ponds, liming, fertilization, stocking of milkfish logs, management of water quality, pest and disease control, and harvesting. Based on observations made, the growth in length and weight of milkfish develops faster using semi-intensive systems compared to modular systems. The semi-intensive system also speeds up the harvest of milkfish, which are generally 6 months to 4 months.

1. Introduction

Milkfish farming in Indonesia shows good prospects [1] that increased production by 9.75% from 2011-2015 with the highest production of 672,196 tons in 2015 2015 [1]. The high production is in line with the shift of consumers in meeting the needs of animal protein from red meat to white meat (fish meat), even the contribution of fish protein to the consumption of animal protein in Indonesian people reaches 57% [3]. [4] Milkfish is a commodity that experienced the highest increase in consumption value in 2009-2013, which is 24, 55% [4].

Milkfish enlargement and hatchery technology has been mastered and developed in the community. Technically the use of technology is able to double production yields and the efficiency of production factors. In Indonesia, the cultivation technology that is developing is traditional (modular) and semi-intensive

Comment [G1]: It is true ?

Comment [G3]: tidied up, please

Comment [G2]: and

Comment [G4]: centers?

Comment [G5]: use terms that are commonly used scientifically

technology. Modular system is a way of maintenance by moving from one plot to another before harvest time in the hope that it will be able to optimize water quality and the availability of natural food continuously during [5]. The characteristics of semi-intensive shrimp ponds are that they have a pond area in a plot of 1-3 ha / plot in a rectangular shape. In the map is equipped with inlet and outlet channels. There is a diagonal caren that leads from the inlet and empties into the outlet channel on each plot [6].

Strategies to increase production, namely the regulation of the level of density, good environmental conditions, adequate feeding and the right density will increase fish growth. The main differences from the modular and semi-intensive systems are feeding, fish density, pond construction and milkfish growth. Therefore, this study was conducted to find out the techniques of milkfish enlargement directly and the differences in the growth of milkfish in the modular and semi-intensive systems at the Center for Brackish Aquaculture Fisheries (BBPBAP) Jepara.

2. Materials and Methods

2.1 Place and time

This study was conducted on December 17, 2018 - January 31, 2019 at BBPBAP, Jepara, Central Java.

2.2 Study Methods

The work method used in this study is to use the active participation method. Data is collected by observation, direct interviews with related parties, and literature study.

3. Results And Discussion

3.1 Water Quality Management

Water quality in milkfish enlargement ponds in BBPBAP Jepara is measured every day and then averaged every day. This measurement aims to determine water conditions and fluctuations that can affect the growth of milkfish. Water quality measurement data can be seen in Figure 1 and 2 below. **Comment [G10]:** What does it mean? During what?

Comment [G11]: Not clear, explain starting from the materials and equipment, research methods, research procedures, what parameters, and data analysis

40 30 20 10 0 DO pH Suhu Salinity Modular Semi Intensif

Figure 1. Morning water quality measurement results (06.30-07.00)

Figure 2. Afternoon water quality measurements results (17.30-18.00)

Salinity in modular ponds is higher than in semi-intensive systems because water changes are very rare. Increased rainfall in the second week resulted in dilution of pond water added and decreased salinity. [7] The good salinity for growth of milkfish ranges from 20-30 ppt. Salinity in modular and semi-intensive systems on average experiences the same fluctuations. The pH value obtained in milkfish ponds requires monitoring because according to [1], the acidity level of milkfish ponds ranges from 7.5 to 8.5. The pH of modular systems is on average higher than semi-intensive systems. [8] The added that daily fluctuations in pH less than 0.5 can cause physiological disorders, ammonia toxicity levels and the presence of natural food such as mosses, plankton, and kelekap.

Temperature in ponds of modular and semi-intensive systems is higher in the afternoon than in the morning because there is accumulation of heat during the day. The temperature in the modular system ponds is also higher than in semi-intensive systems. [9] Solar radiation, temperature, air, weather, and climate will influence the amount of water temperature. [10] The optimum temperature for milkfish cultivation is 29-30°C, with a threshold below 26°C and a range above 32°C. The dissolved oxygen content in the morning is lower in modular ponds than in semi-intensive ponds due to the accumulation of carbon dioxide. Carbon dioxide accumulation in modular ponds originating from milkfish and primary producers is dense while semi-intensive ponds are originated from milkfish and primary producers that

Comment [G12]: in the list of references, the seventh reference is about the diseasis, not in accordance with this statement

are not too dense. The conveyed the level of dissolved oxygen in water influenced by organisms in the area including plankton as primary productivity. Oxygen fluctuations between day and night in a waters are an indicator of the density of organisms including plankton as primary productivity[8].

3.2 Milkfish Growth

The growth of milk fish can be determined by sampling the length and weight which is done once every 16 days. Growth sampling is done by measuring the total length of milkfish manually using a ruler, then weighed one by one to determine the development of body weight. Sampling is carried out during maintenance and before harvest with the aim of determining the size of production and also plays a role in determining the price of fish produced. Milkfish Growth Sampling Data can be seen in the following Figure 3 and 4.

The growth in length and absolute weight of milkfish in modular ponds is lower than in semi-intensive ponds because modular ponds do not use artificial feed (pellets) while the same density is 12,000 heads. The speed of growth depends on the amount of feed consumed, the amount of protein content contained in the feed, water quality, and other factors such as heredity, age and endurance and the ability of the **Comment [G13]:** it needs to be added to the discussion about the relationship of water quality with the growth of milkfish

Comment [G14]: for data analysis you don't use statistical analysis, so it doesn't explain the length and weight is lower than

Comment [G15]: whether the pellet is natural feed???

fish to use feed. When protein is low, slow fish growth can occur[11]. Protein plays an important role in the preparation of fish tissue and organs [12]. Milkfish survival rate in modular and semi intensive ponds 83%lebih tinggi dari standart ketentuan 80% [13]. The low survival of a cultivation biota is influenced by several factors, one of which is inappropriate feed nutrition[14]. This is supported [15] which states that fish have a great immune system against disease as long as their body condition is not weakened by a cause.

Based on the growth sampling and milkfish enlargement techniques above, the modular and semi-intensive systems have a number of differences that can be seen in Table 1 below.

Table 1. Differentations of Modular and Semi Intensive system

| Difference | Modular System | Semi Intensive System |
|-------------------------|-------------------|--------------------------|
| Feed | - | + |
| Ferris wheel | - | + |
| Maintenance Duration | 6 Month | 3 Month |
| Pond construction | Traditional | HDPE plastic |
| Growth | Late | Fast |

4. Conclusion

Based on studies that have been carried out at BBPBAP Jepara, it can be concluded that:

1. Differences in modular and semi-intensive systems in terms of pellet use, pond construction, wheel availability, growth, and duration of maintenance.

2. Semi-intensive system is more effective to increase the growth of milkfish and

shorten the duration of aquaculture.

5. Suggestion

1. Further sampling is needed to obtain more diverse and valid data.

2. The density of milk fish in modular ponds needs to be reviewed.

3. We recommend that biosecurity around milkfish ponds be increased, because the location of the pond is directly adjacent to the residential areas.

Comment [G16]: What does it mean???
Comment [G17]: Add the composition

of feed to the milkfish culture system in this study

Comment [G18]: Data analysis in this study does not use statistical analysis, so it is not possible to distinguish between modular systems and enlargement

Comment [G19]: Data analysis in this study does not use statistical analysis, so it is not possible to distinguish between modular systems and enlargement
